Algorithm Engineering für grundlegende Datenstrukturen und Algorithmen

Peter Sanders

Was sind die schnellsten implementierten Algorithmen

für das 1×1 der Algorithmik:

Listen, Sortieren, Prioritätslisten, Sortierte Listen, Hashtabellen,

Graphenalgorithemen?

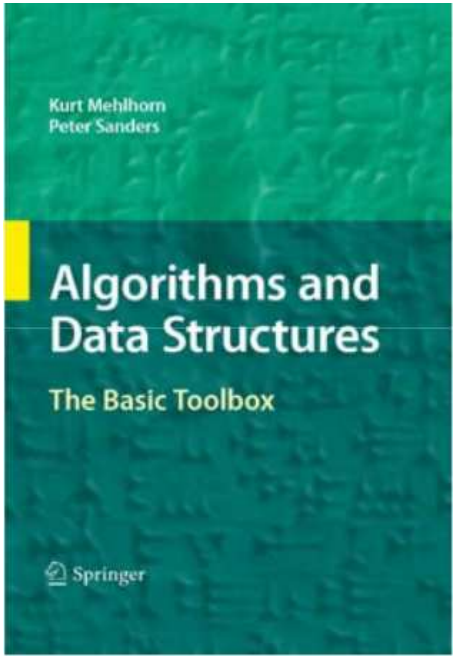
Nützliche Vorkenntnisse

- Informatik I/II
- Algorithmentechnik (gleichzeitig hören vermutlich OK)
- etwa Rechnerarchitektur (oder Ct lesen ;-)
- passive Kenntnisse von C/C++

Vertiefungsgebiet: Algorithmik

Material

- Folien
- wissenschaftliche Aufsätze.
  Siehe Vorlesungshomepage
- Basiskenntnisse: Algorithmenlehrbücher,
  z.B. Mehlhorn/Sanders, Cormen et al.



- Mehlhorn Näher: The LEDA Platform of Combinatorial and Geometric Computing. Gut für die fortgeschrittenen Papiere.

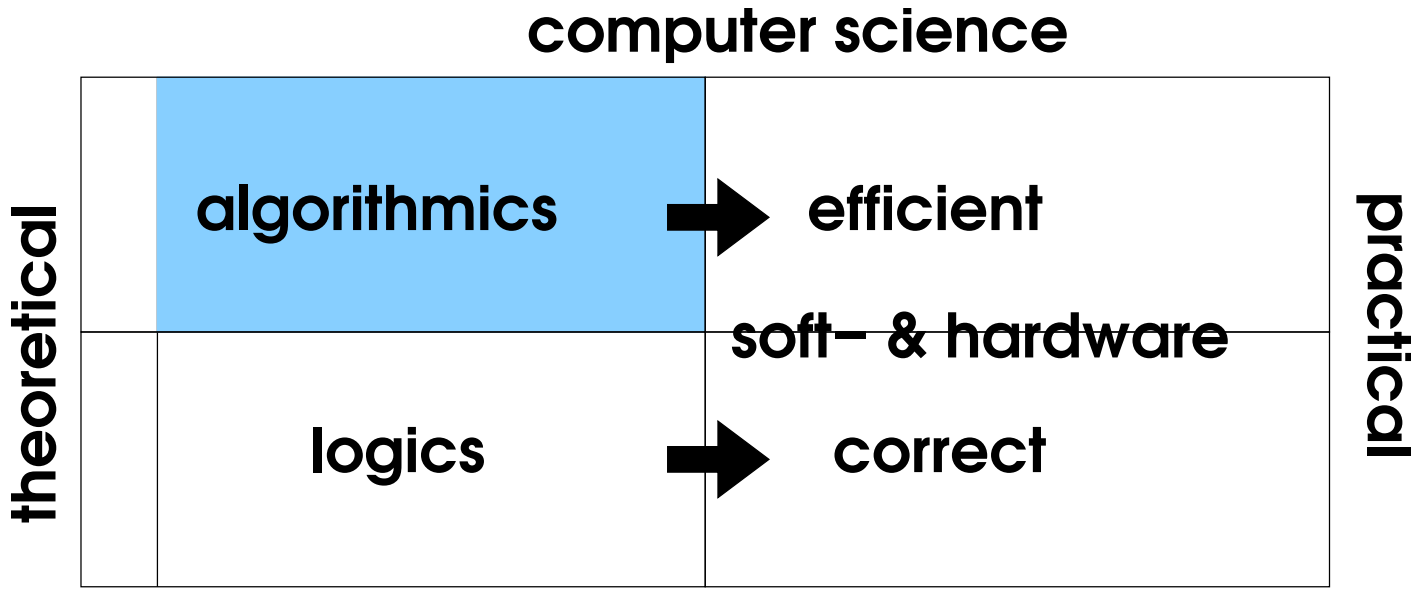
Überblick

- Was ist Algorithm Engineering, Modelle, . . .
- Erste Schritte: Arrays, verkettete Listen, Stacks, FIFOs,. . .
- Sortieren rauf und runter
- Prioritätslisten
- Sortierte Listen
- Hashtabellen
- Minimale Spannbäume
- Kürzeste Wege
- Ausgewählte fortgeschrittene Algorithmen, z.B. maximale Flüsse

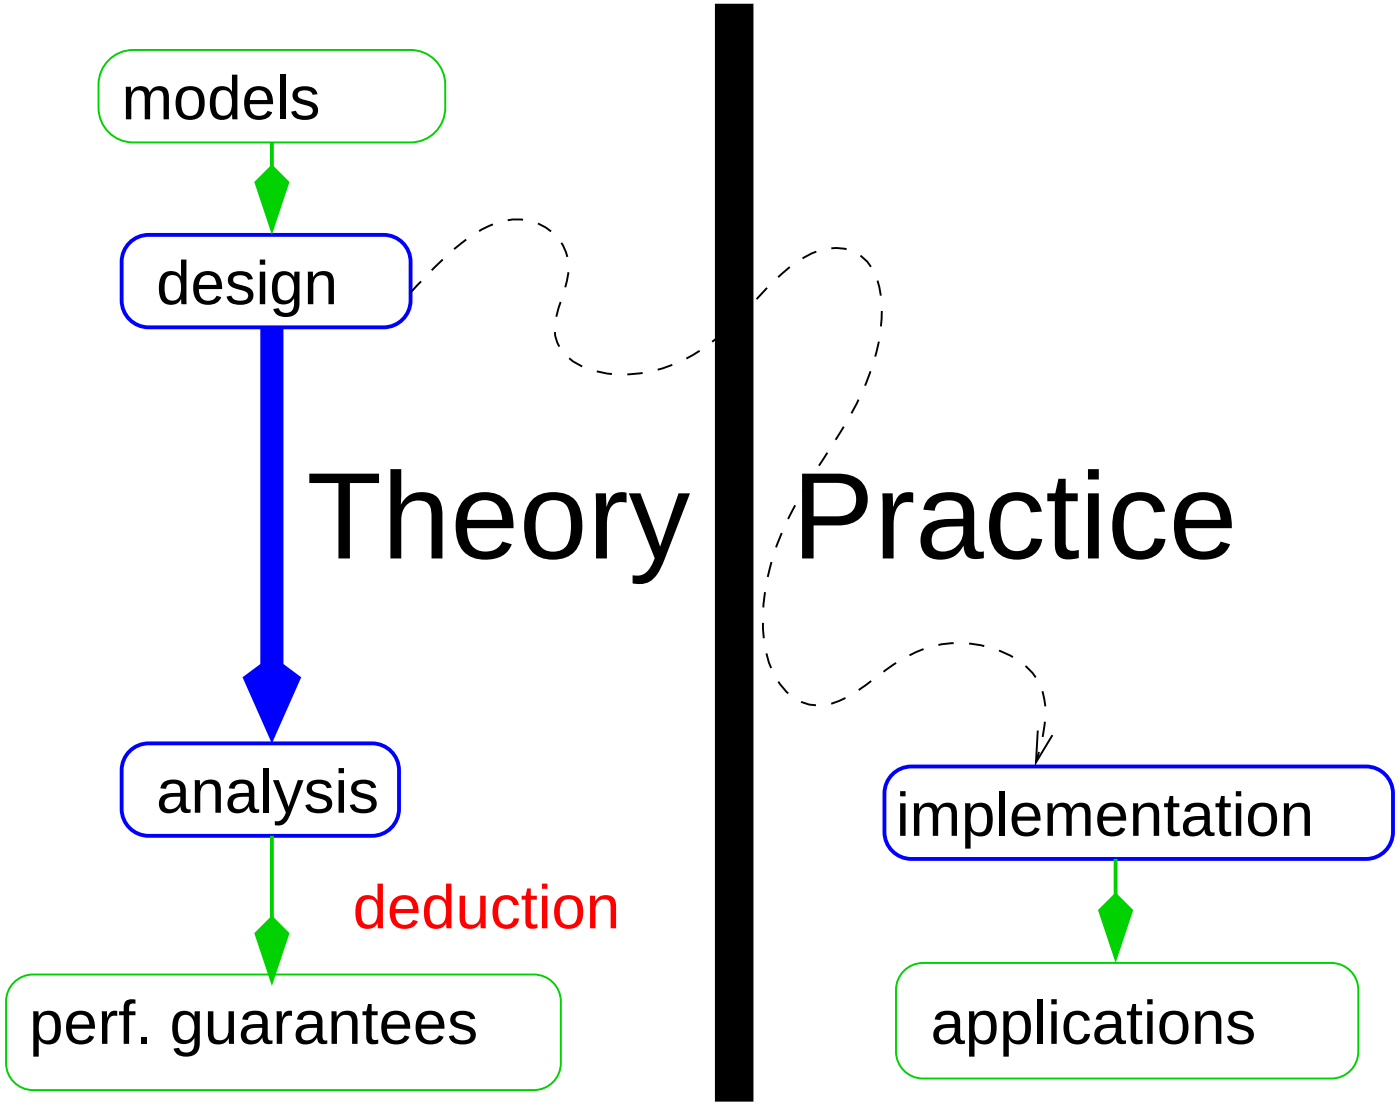
Methodik: in Exkursen

Algorithmics

= the systematic design of efficient software and hardware



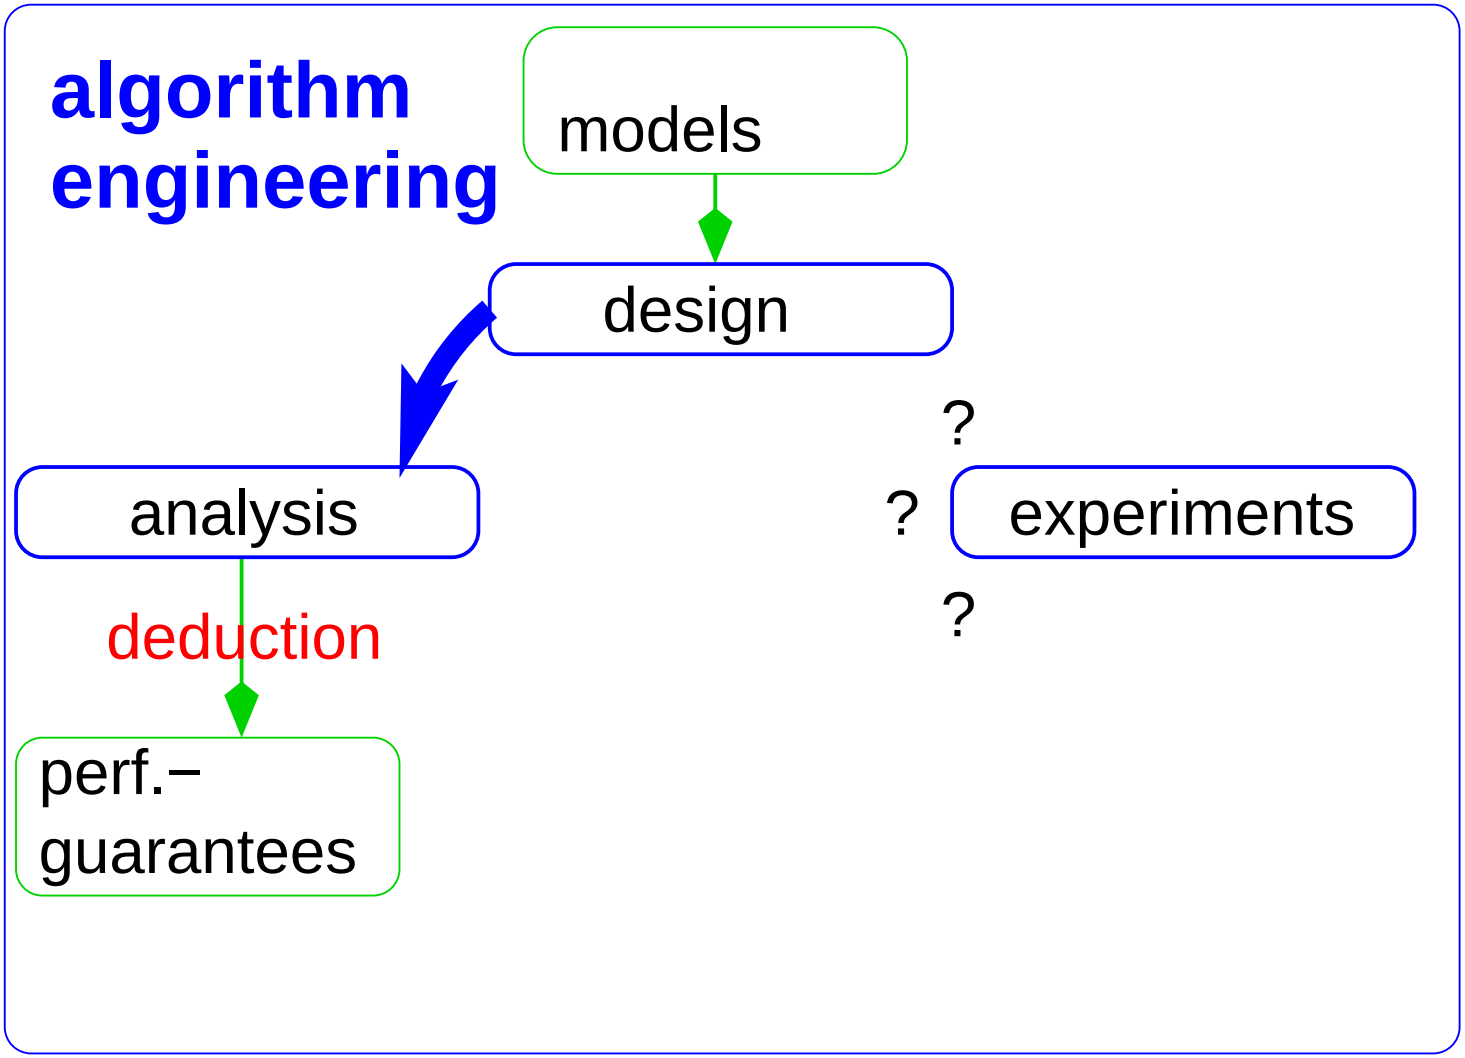
(Caricatured) Traditional View: Algorithm Theory



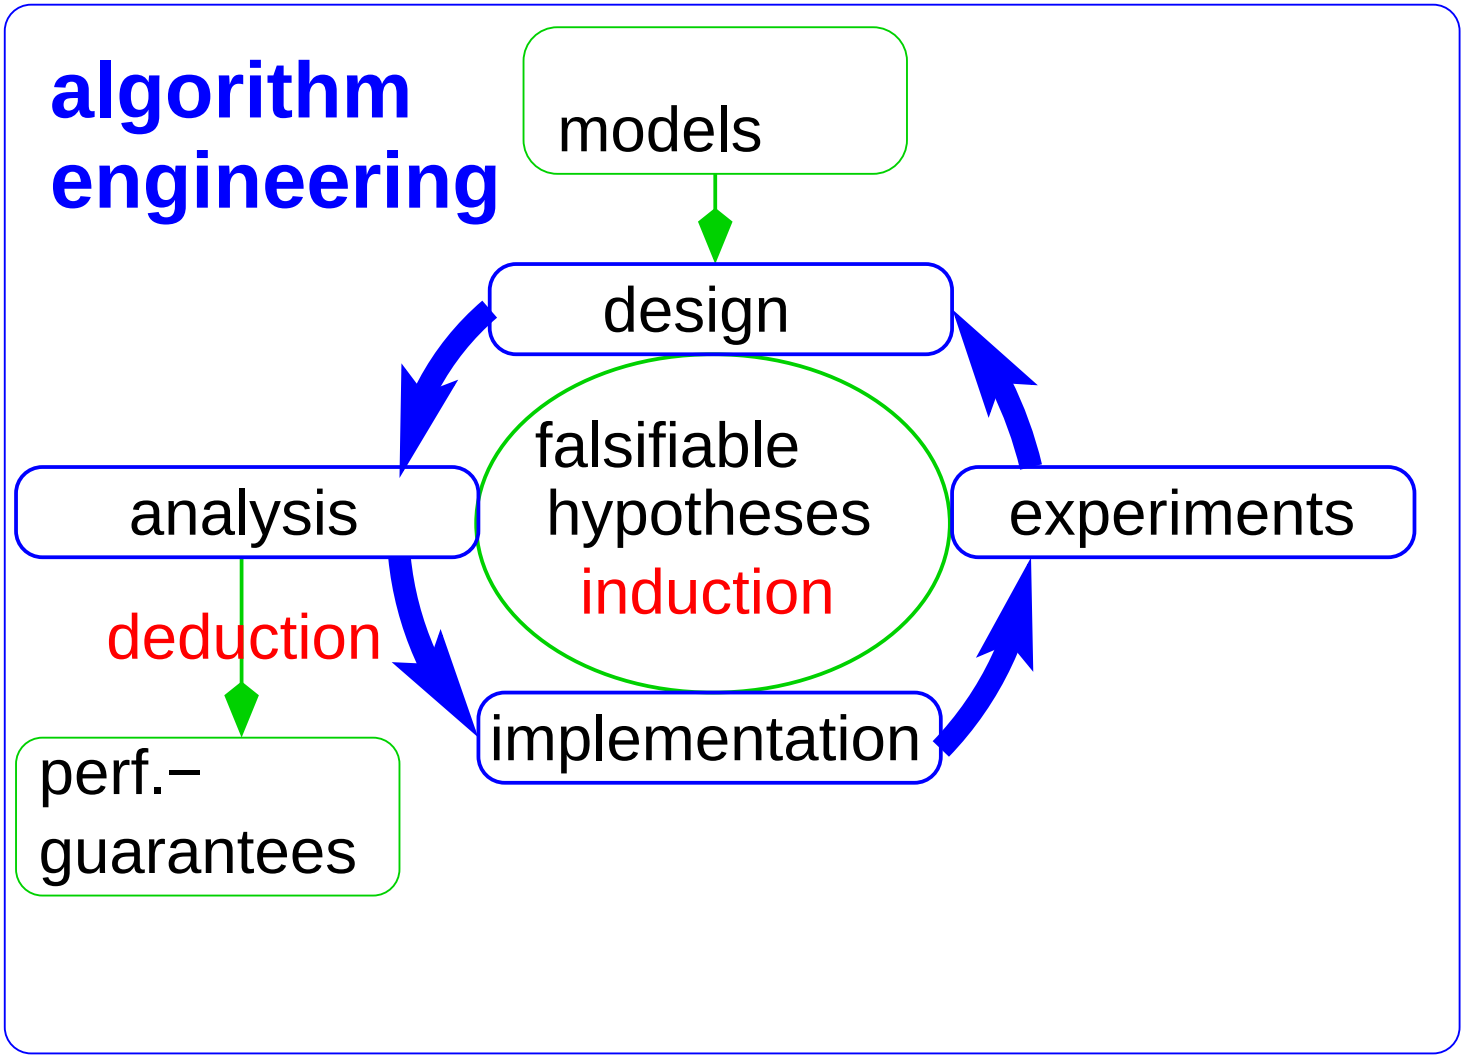
Gaps Between Theory & Practice

Theory	$\longleftrightarrow$	**Practice**
simple 	**appl. model**	 complex
simple 	**machine model**	 real
complex 	**algorithms**	FOR simple
advanced 	**data structures**	 arrays,. . .
worst case max	**complexity measure**	 inputs
asympt. $\mathcal{O}(\cdot)$	**efficiency**	42% constant factors

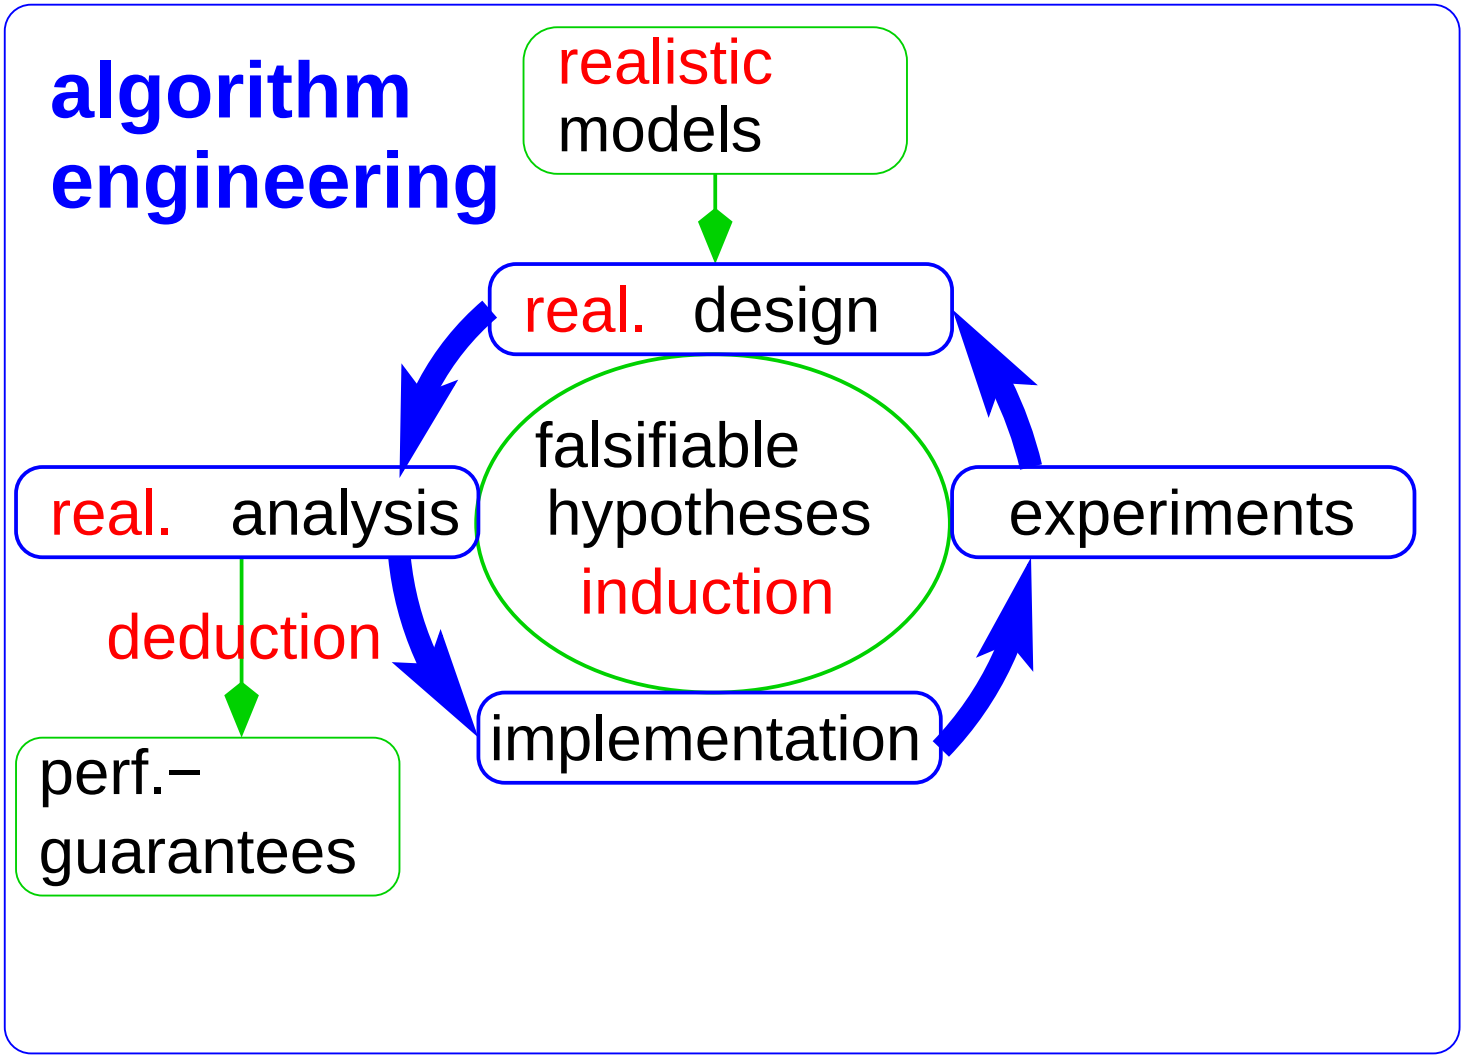
Algorithmics as Algorithm Engineering



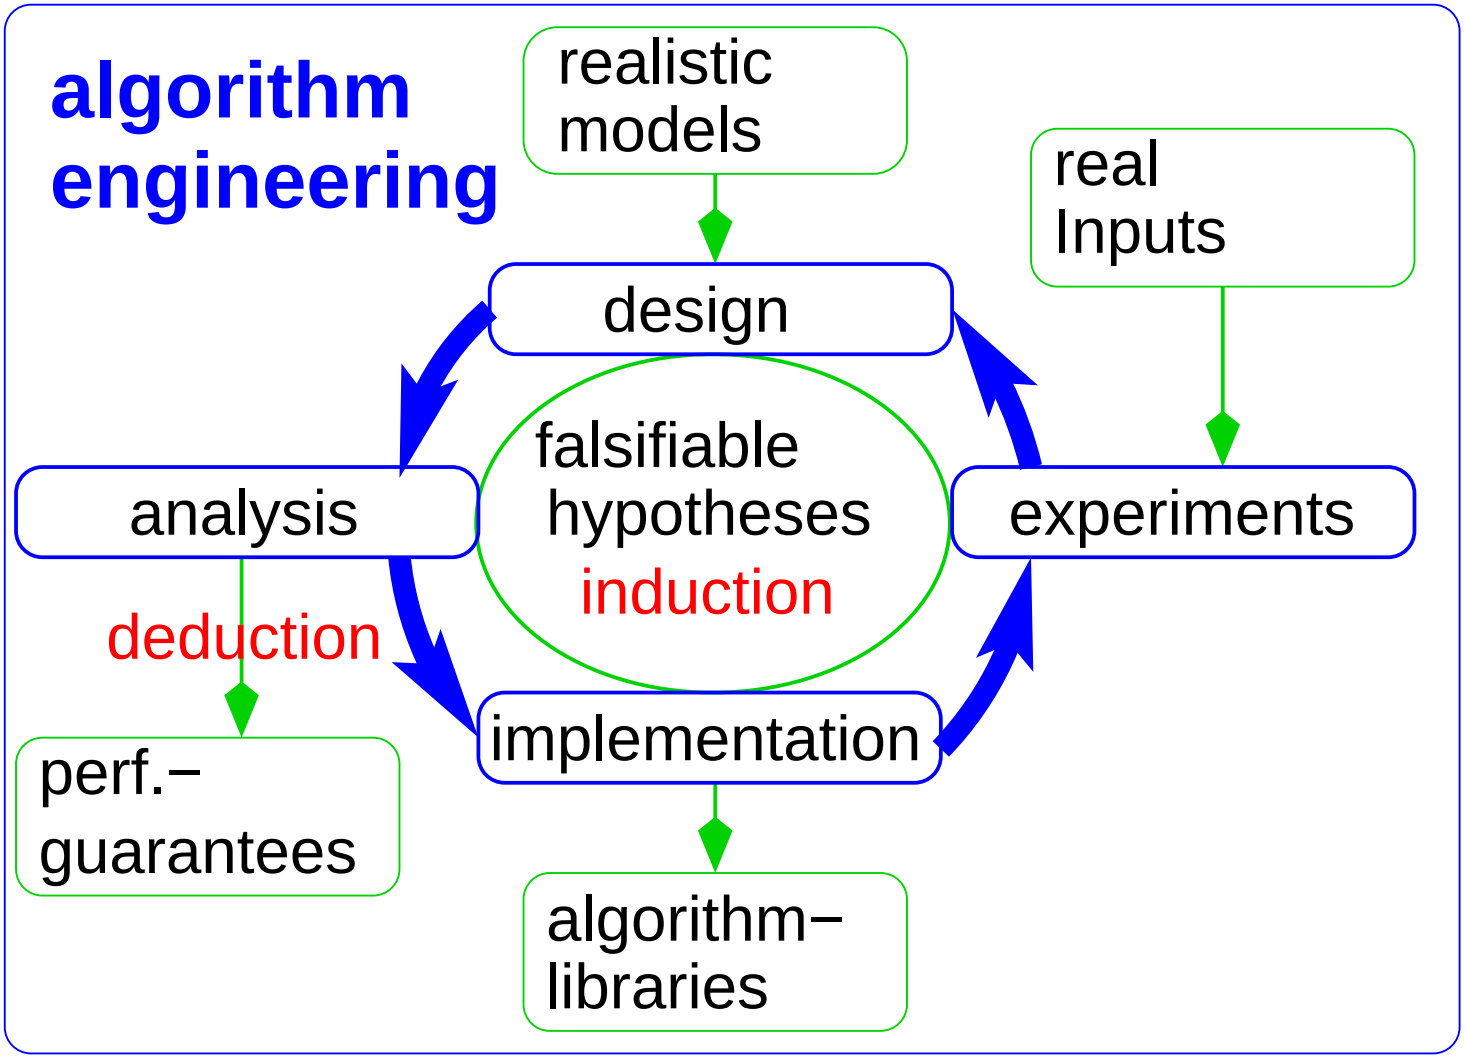
Algorithmics as Algorithm Engineering



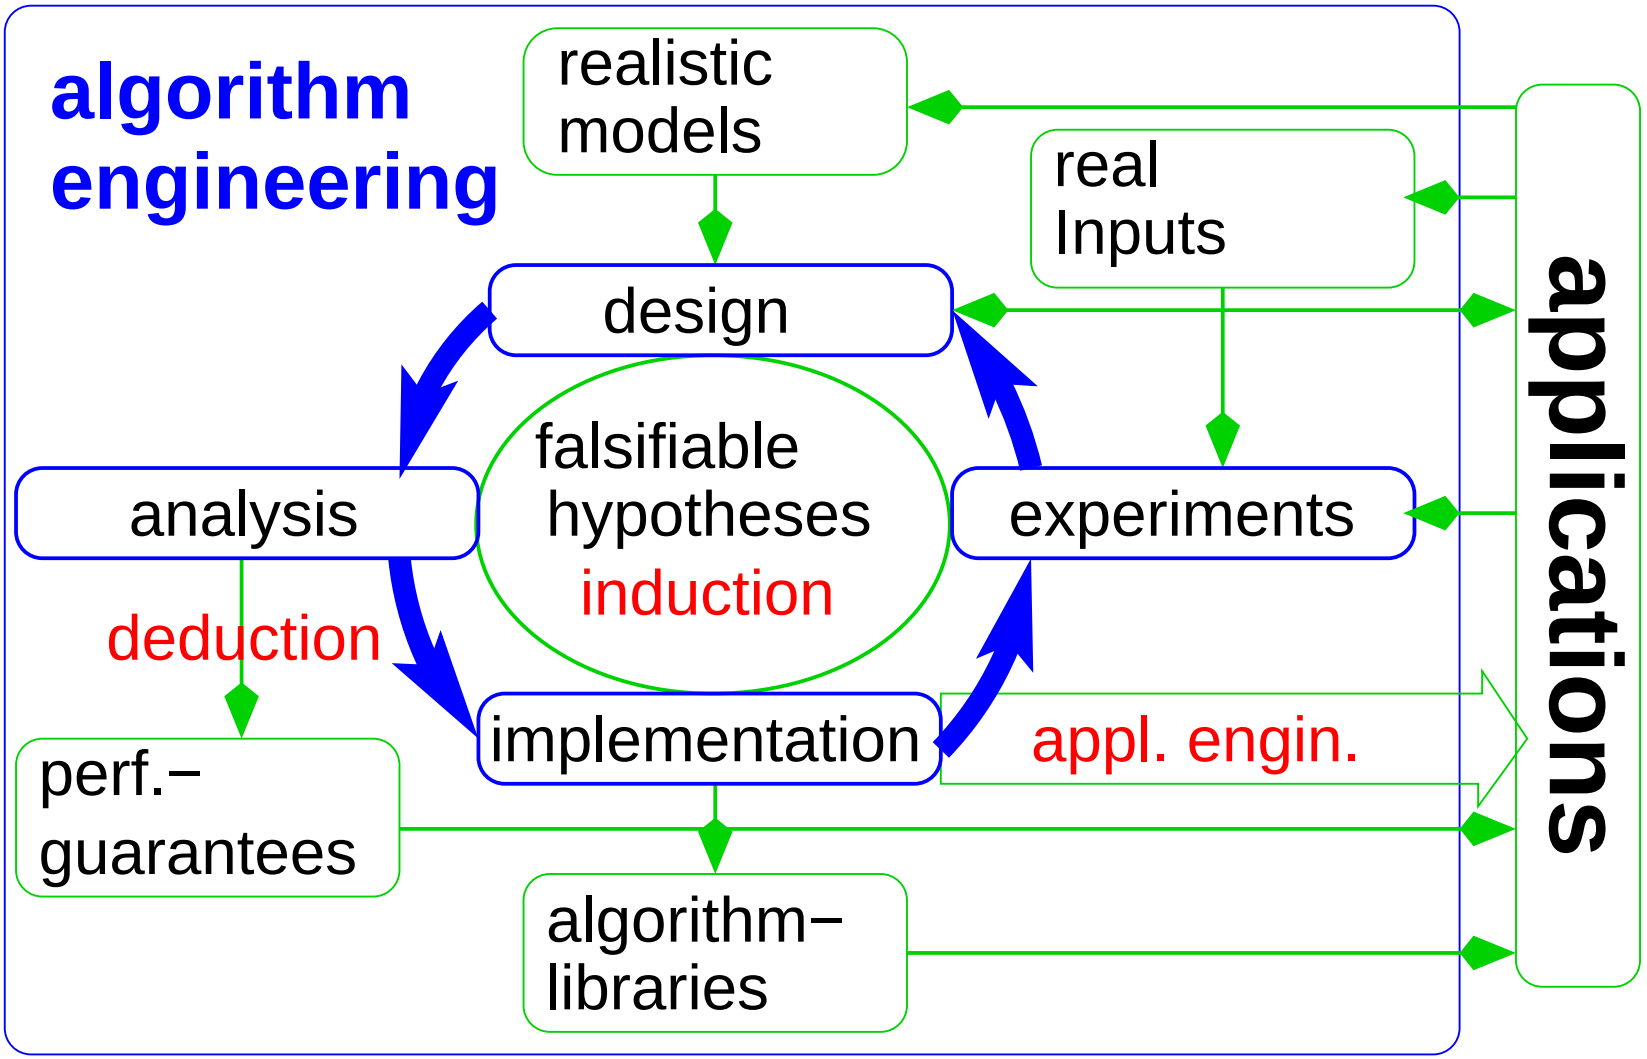
Algorithmics as Algorithm Engineering



Algorithmics as Algorithm Engineering

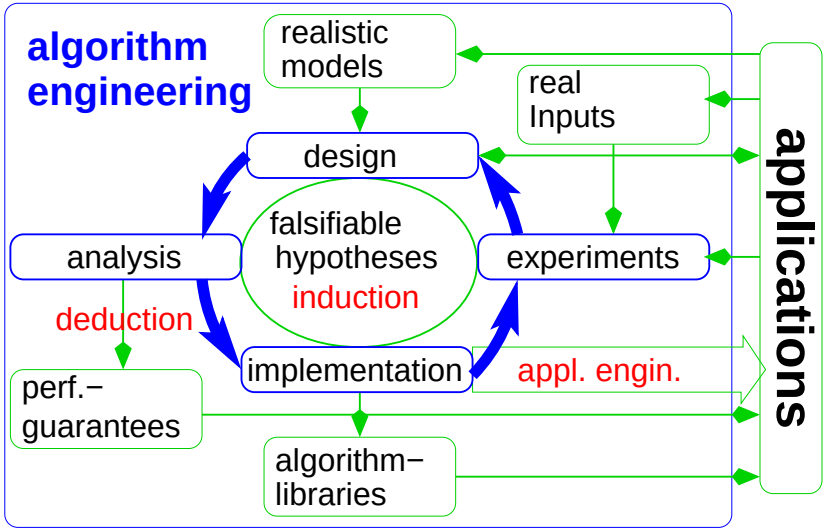


Algorithmics as Algorithm Engineering



Goals

- bridge gaps between theory and practice
- accelerate transfer of algorithmic results into applications
- keep the advantages of theoretical treatment:
  generality of solutions and
  reliabiltiy, predictabilty from performance guarantees



Bits of History

1843– Algorithms in theory and practice

1950s,1960s Still infancy

1970s,1980s Paper and pencil algorithm theory.

Exceptions exist, e.g., [D. Johnson]

1986 Term used by [T. Beth],

lecture “Algorithmentechnik” in Karlsruhe.

1988– Library of Efficient Data Types and Algorith

(LEDA) [K. Mehlhorn]

1997– Workshop on Algorithm Engineering

$\rightsquigarrow$ ESA applied track [G. Italiano]

1997 Term used in US policy paper [Aho, Johnson, Karp, et. al]

1998 Alex workshop in Italy $\rightsquigarrow$ ALENEX

Warum diese Vorlesung?

- Jeder Informatiker kennt einige Lehrbuchalgorithmen
  $\rightsquigarrow$ wir können gleich mit Algorithm Engineering loslegen
- Viele Anwendungen profitieren
- Es ist frappierend, dass es hier noch Neuland gibt
- Basis für Studien- Diplomarbeiten

Was diese Vorlesung nicht ist:

Keine wiedergekäute Algorithmentechnik o.Ä.

- Grundvorlesungen “vereinfachen” die Wahrheit oft
- z.T. fortgeschrittene Algorithmen
- steilere Lernkurve
- Implementierungsdetails
- Betonung von Messergebnissen

Was diese Vorlesung nicht ist:

Keine Theorievorlesung

- keine (wenig?) Beweise
- Reale Leistung vor Asymptotik

Was diese Vorlesung nicht ist:

Keine Implementierungsvorlesung

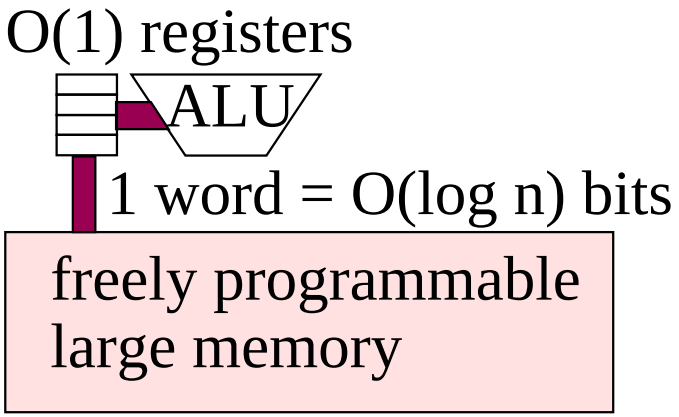
- Etwas Algorithmenanalyse,. . .
- Wenig Software Engineering
- Keine Implementierungsübungen (aber, stay tuned für ein Praktikum)

Exkurs: Maschinenmodelle

RAM/von Neumann Modell

Analyse: zähle Maschinenbefehle — load, store, Arithmetik, Branch,. . .

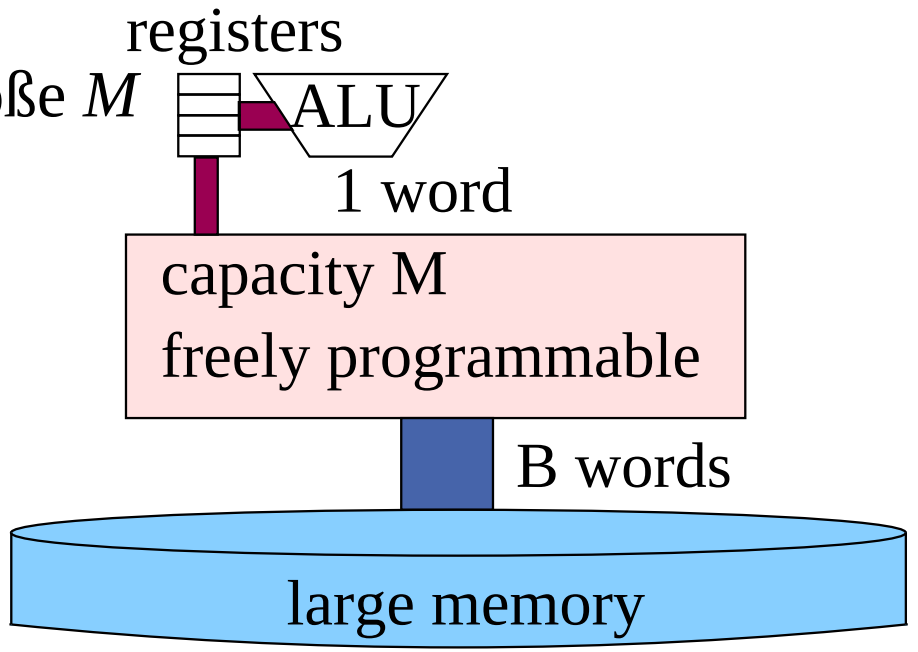
- Einfach
- Sehr erfolgreich
- zunehmrend unrealistisch
  weil reale Hardware
  immer komplexer wird



Das Sekundärspeichermodell

M: Schneller Speicher der Größe *M*

B: Blockgröße



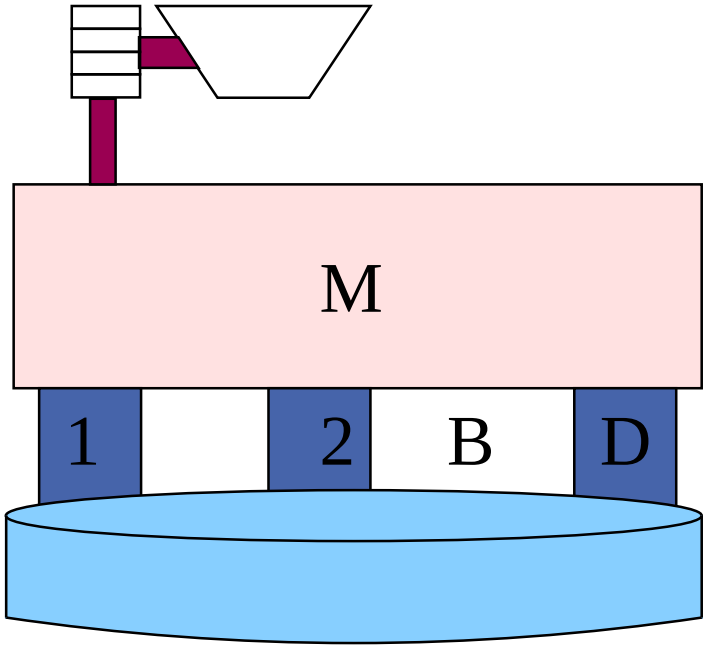
Analyse: zähle (nur?) Blockzugriffe (I/Os)

Interpretationen des Sekundärspeichermodelle

	Externspeicher	Caches
großer Speicher	Platte(n)	Hauptspeicher
M	Hauptspeicher	ein cache level
B	Plattenblock (MBytes!)	Cache Block (16–256) Byte

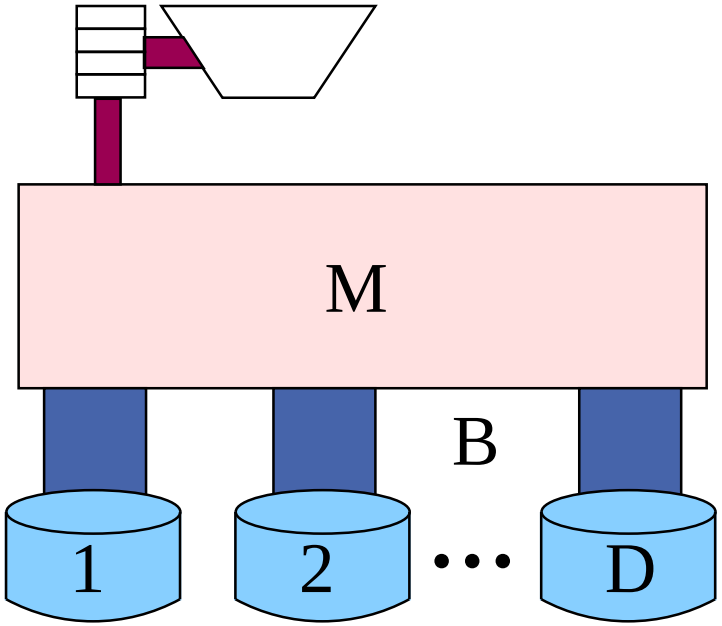
Ggf. auch zwei cache levels.

Parallele Platten



Mehrkopfmodell

[Aggarwal Vitter 88]



unabhängige Platten

[Vitter Shriver 94]

Mehr Modellaspekte

- Instruktionsparallelismus (Superscalar, VLIW, EPIC,SIMD,...)
- Pipelining
- Was kostet branch misprediction?
- Multilevel Caches (gegenwärtig 2–3 levels) $\rightsquigarrow$ “cache oblivious algorithms”
- Parallele Prozessoren, Multithreading
- Kommunikationsnetzwerke
- ...

1 Arrays, Verkettete Listen und abgeleitete Datenstrukturen

Bounded Arrays

Eingebaute Datenstruktur.

Größe muss von Anfang an bekannt sein

Unbounded Array

z.B. `std::vector`

pushBack: Element anhängen

popBack: Letztes Element löschen

Idee: verdopple wenn der Platz ausgeht

halbiere wenn Platz verschwendet wird

Wenn man das richtig macht, brauchen

n pushBack/popBack Operationen Zeit $\mathcal{O}(n)$

Algorithmese: pushBack/popBack haben konstante amortisierte Komplexität Was kann man falsch machen?

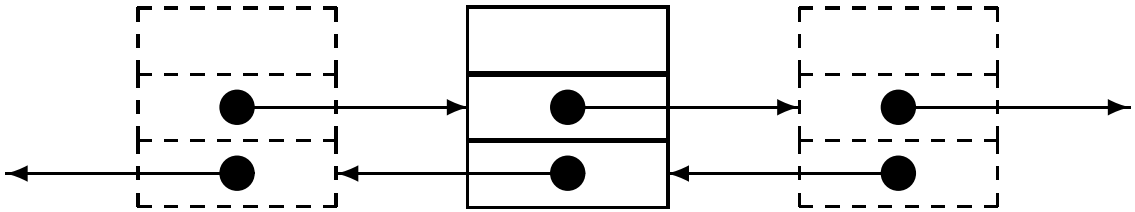
Doppelt verkettete Listen

Class Item **of** Element // one link in a doubly linked list

e : Element

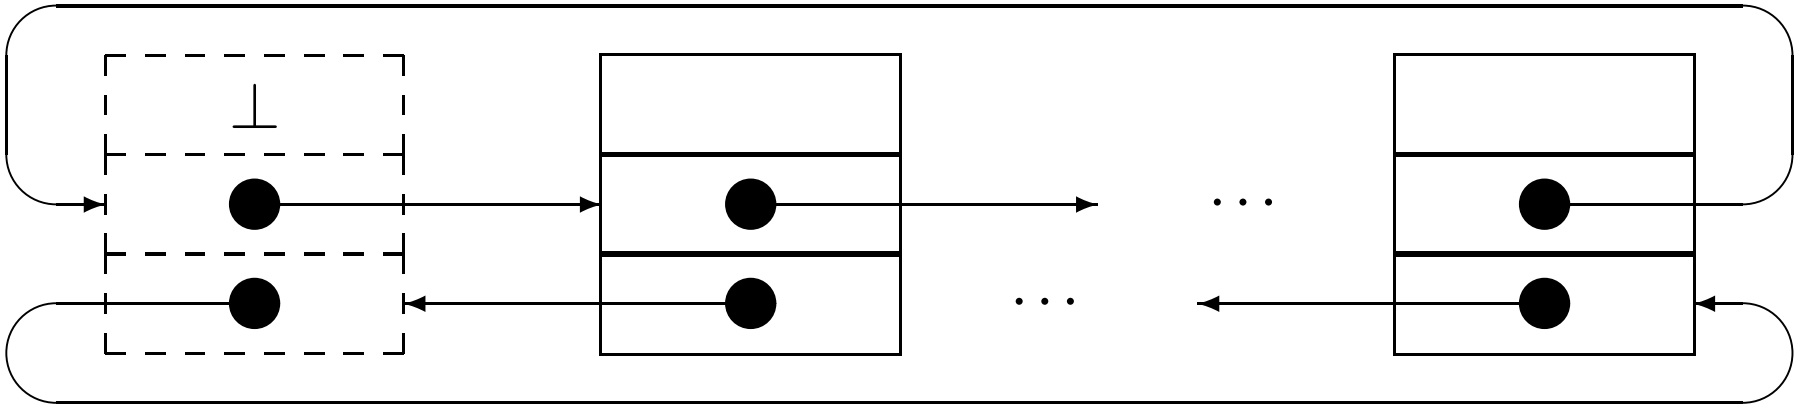
next : Handle //

prev : Handle



invariant next→prev=prev→next=**this**

Trick: Use a dummy header



Procedure splice(a,b,t : Handle)

assert b is not before $a \wedge t \notin \langle a, \ldots, b \rangle$

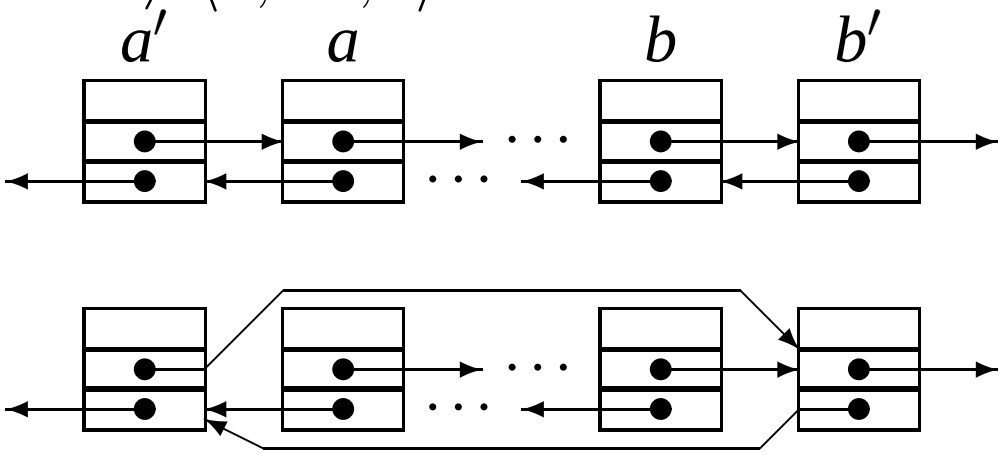
//Cut out $\langle a, \ldots, b \rangle$

a' := a→prev

b' := b→next

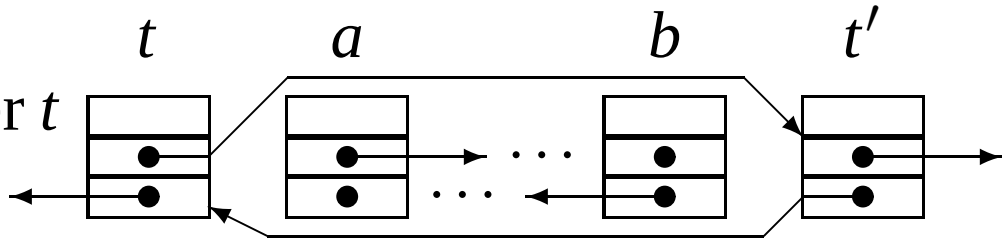
a' →next := b' //

b' →prev := a' //



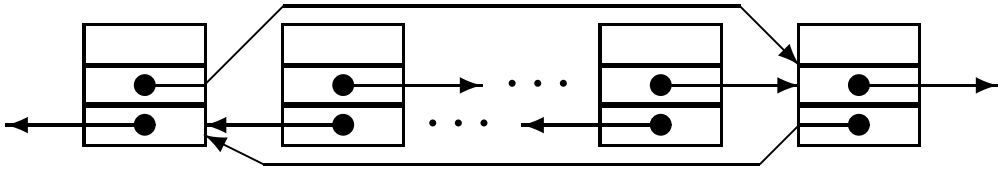
//insert $\langle a, \ldots, b \rangle$ after t

t' := t→next //



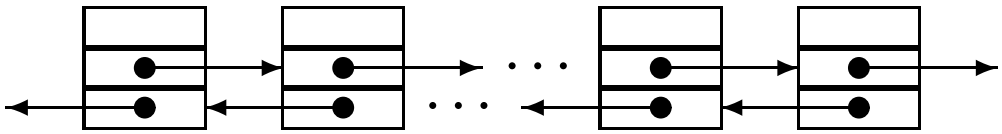
b→next := t' //

a→prev := t //

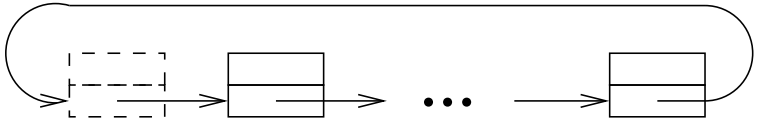


t →next := a //

t' →prev := b //



Einfach verkettete Listen



Vergleich mit doppelt verketteten Listen

- Weniger Speicherplatz
- Platz ist oft auch Zeit
- Eingeschränkter z.B. kein delete
- Merkwürdige Benutzerschnittstelle, z.B. deleteAfter

Speicherverwaltung für Listen

- kann leicht 90 % der Zeit kosten!
- Lieber Elemente zwischen (Free)lists herschieben als echte `mallocs`
- Alloziere viele Items gleichzeitig
- Am Ende alles freigeben?
- Speichere „parasitär“. z.B. Graphen:
  Knotenarray. Jeder Knoten speichert ein ListItem
  $\rightsquigarrow$ Partition der Knoten kann als verkettete Listen gespeichert werden
  $\rightsquigarrow$ MST, shortest Path

Challenge: garbage collection, viele Datentypen

$\rightsquigarrow$ auch ein Software Engineering Problem hier nicht

Beispiel: Stack

	SList	B-Array	U-Array
dynamisch	+	–	+
Platzverschwendung	pointer freigeben?	zu groß?	zu groß?
Zeitverschwendung	cache miss	+	umkopieren
worst case time	(+)	+	–

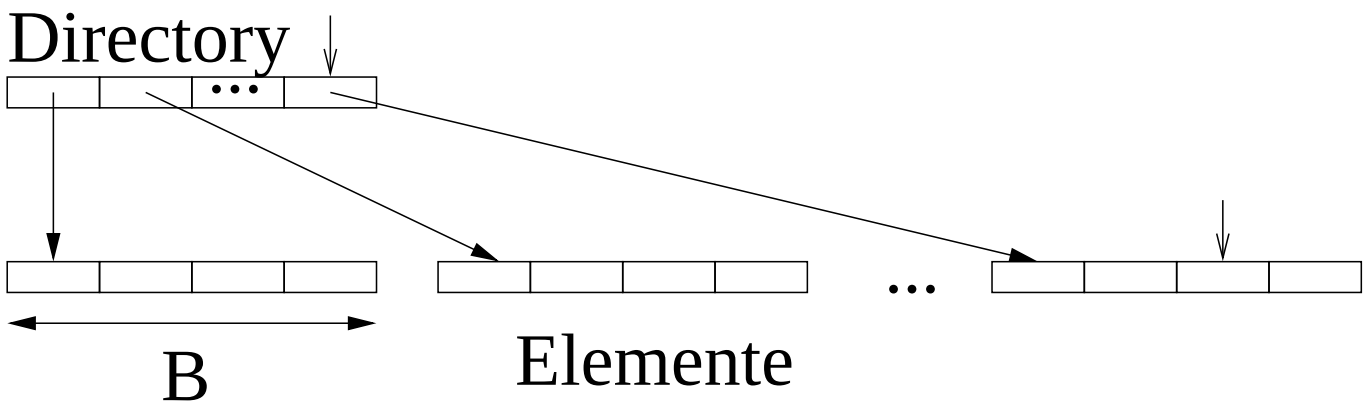
Wars das?

Hat jede Implementierung gravierende Schwächen?

The Best From Both Worlds

	hybrid
dynamisch	+
Platzverschwendung	$n/B + B$
Zeitverschwendung	+
worst case time	+

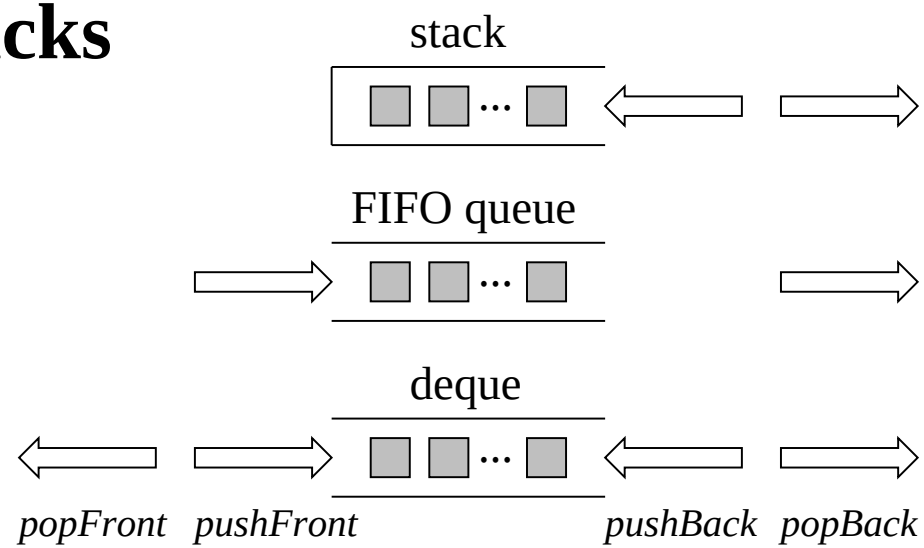
Eine Variante

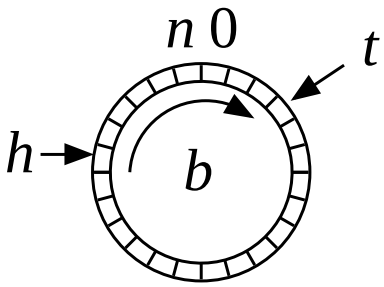


– Reallozierung im top level $\rightsquigarrow$ nicht worst case konstante Zeit

\+ Indizierter Zugrif auf $S[i]$ in konstanter Zeit

Beyond Stacks





FIFO: BArray $\longrightarrow$ cyclic array

Aufgabe: Ein Array, das “[i]” in konstanter Zeit und einfügen/löschen von Elementen in Zeit $\mathcal{O}(\sqrt{n})$ unterstützt

Aufgabe: Ein externer Stack, der n push/pop Operationen mit $\mathcal{O}(n/B)$ I/Os unterstützt

Aufgabe: Tabelle für hybride Datenstrukturen vervollständigen

Operation	List	SList	UArray	CArray	explanation of '*'
$[\cdot]$	n	n	1	1	
$\lvert\cdot\rvert$	1^*	1^*	1	1	not with inter-list splice
first	1	1	1	1	
last	1	1	1	1	
insert	1	1^*	n	n	insertAfter only
remove	1	1^*	n	n	removeAfter only
pushBack	1	1	1^*	1^*	amortized
pushFront	1	1	n	1^*	amortized
popBack	1	n	1^*	1^*	amortized
popFront	1	1	n	1^*	amortized
concat	1	1	n	n	
splice	1	1	n	n	
findNext,...	n	n	n^*	n^*	cache efficient

Was fehlt?

Fakten Fakten Fakten

Messungen für

- Verschiedene Implementierungsvarianten
- Verschiedene Architekturen
- Verschiedene Eingabegrößen
- Auswirkungen auf reale Anwendungen
- Kurven dazu
- Interpretation, ggf. Theoriebildung

Aufgabe: Array durchlaufen versus zufällig allozierte verkettete Liste

Sorting — Overview

- You think you understand quicksort?
- Avoiding branch mispredictions: Super Scalar Sample Sort
- (Parallel disk) external sorting
- Multicore sorting

Quicksort

Function quickSort(s : Sequence **of** Element) : Sequence **of** Element

if $|s| \leq 1$ **then return** s // base case

pick $p \in s$ uniformly at random // pivot key

a := $\langle e \in s : e < p \rangle$

b := $\langle e \in s : e = p \rangle$

c := $\langle e \in s : e > p \rangle$

return concatenate(quickSort(a), b, quickSort(c))

Engineering Quicksort

- array
- 2-way-Comparisons
- sentinels for inner loop
- inplace swaps
- Recursion on smaller subproblems
  $\rightarrow \mathcal{O}(\log n)$ additional space
- break recursion for small (20–100) inputs, insertion sort
  (not one big insertion sort)

Procedure qSort(a : **Array of** Element; $\ell, r : \mathbb{N}$) // Sort $a[\ell..r]$

  while $r - \ell \geq n_0$ **do** // Use divide-and-conquer

    $j :=$ pickPivotPos(a, l, r)

    swap$(a[\ell], a[j])$ // Helps to establish the invariant

    $p := a[\ell]$

    $i := \ell$; $j := r$

    repeat // a: ℓ $i\rightarrow$ $\leftarrow j$ r

      while $a[i] < p$ **do** $i{+}{+}$ // Scan over elements (A)

      while $a[j] > p$ **do** $j{-}{-}$ // on the correct side (B)

      if $i \leq j$ **then** swap$(a[i], a[j])$; $i{+}{+}$; $j{-}{-}$

    until $i > j$ // Done partitioning

    if $i < \frac{l+r}{2}$ **then** qSort(a, ℓ, j); $\ell := j$

    else qSort(a, i, r) ; $r := i$

  insertionSort$(a[l..r])$ // faster for small $r - \ell$

Picking Pivots Painstakingly — Theory

probabilistically: Expected $1.4n \log n$ element comparisons

median of three: Expected $1.2n \log n$ element comparisons

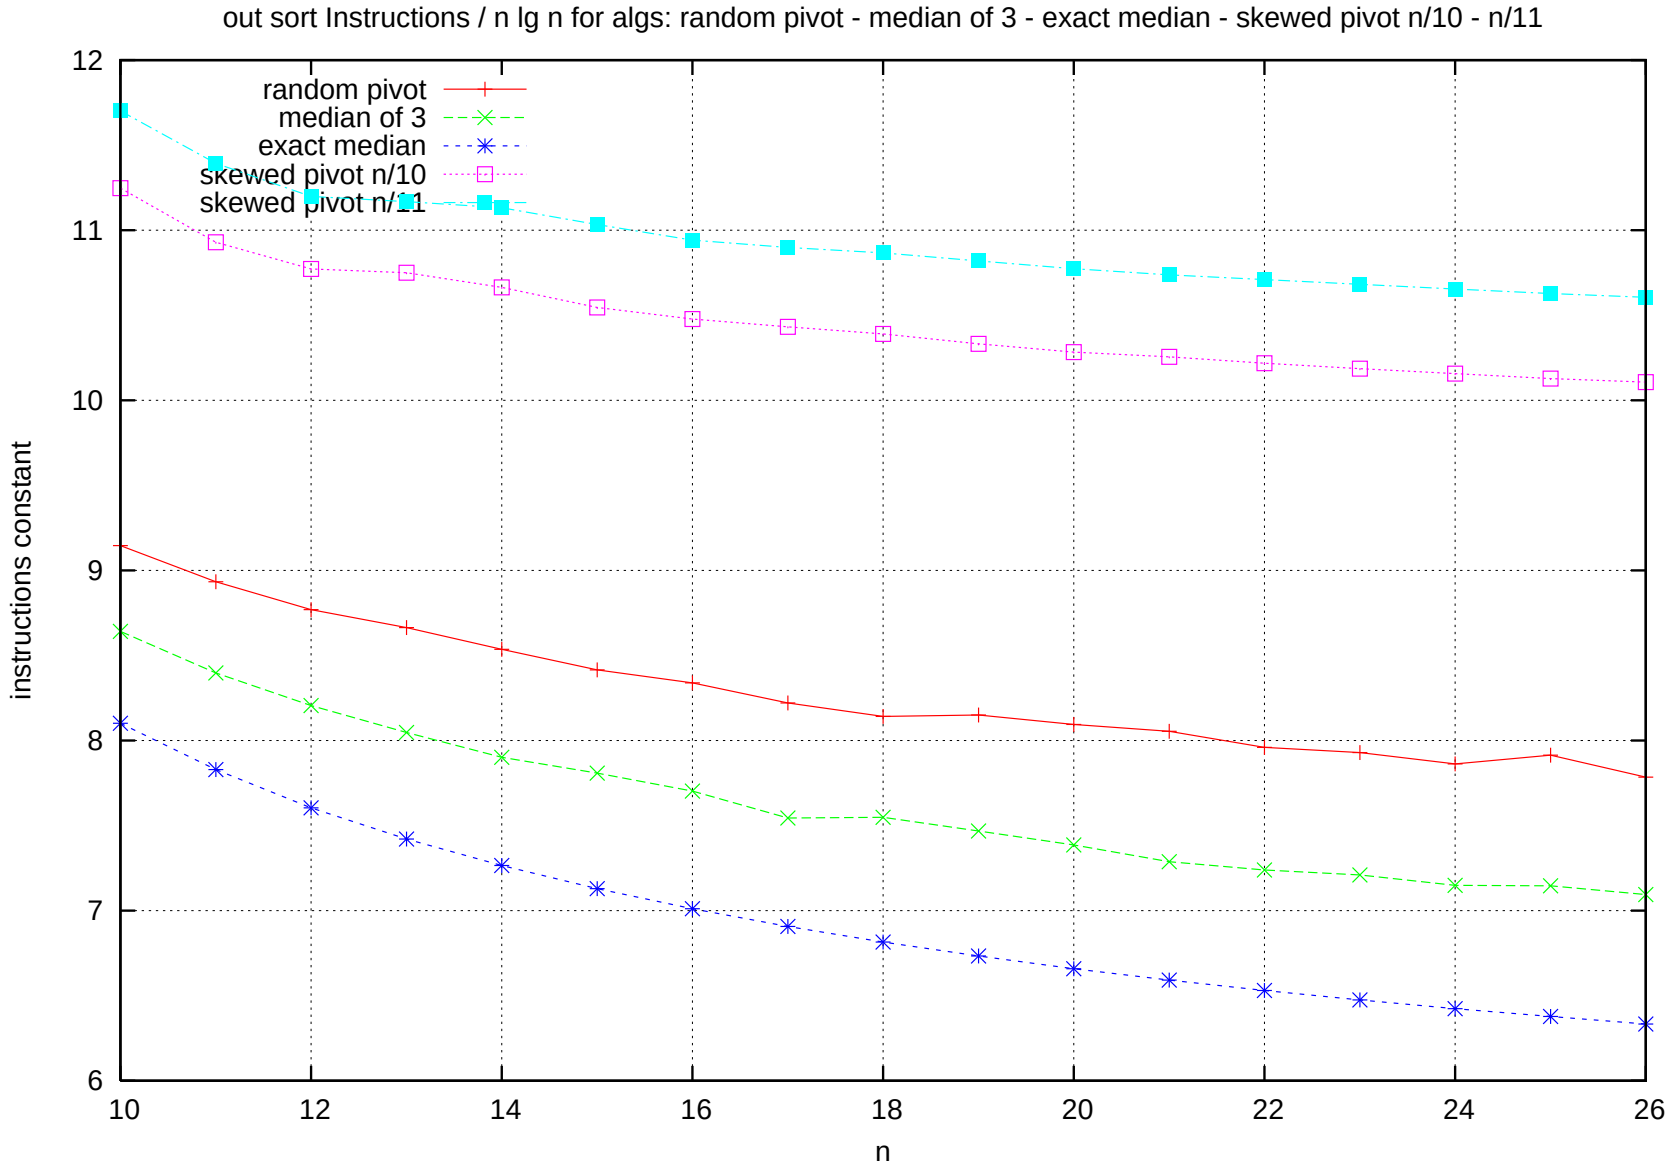
perfect: $\longrightarrow n \log n$ element comparisons

(approximate using large samples)

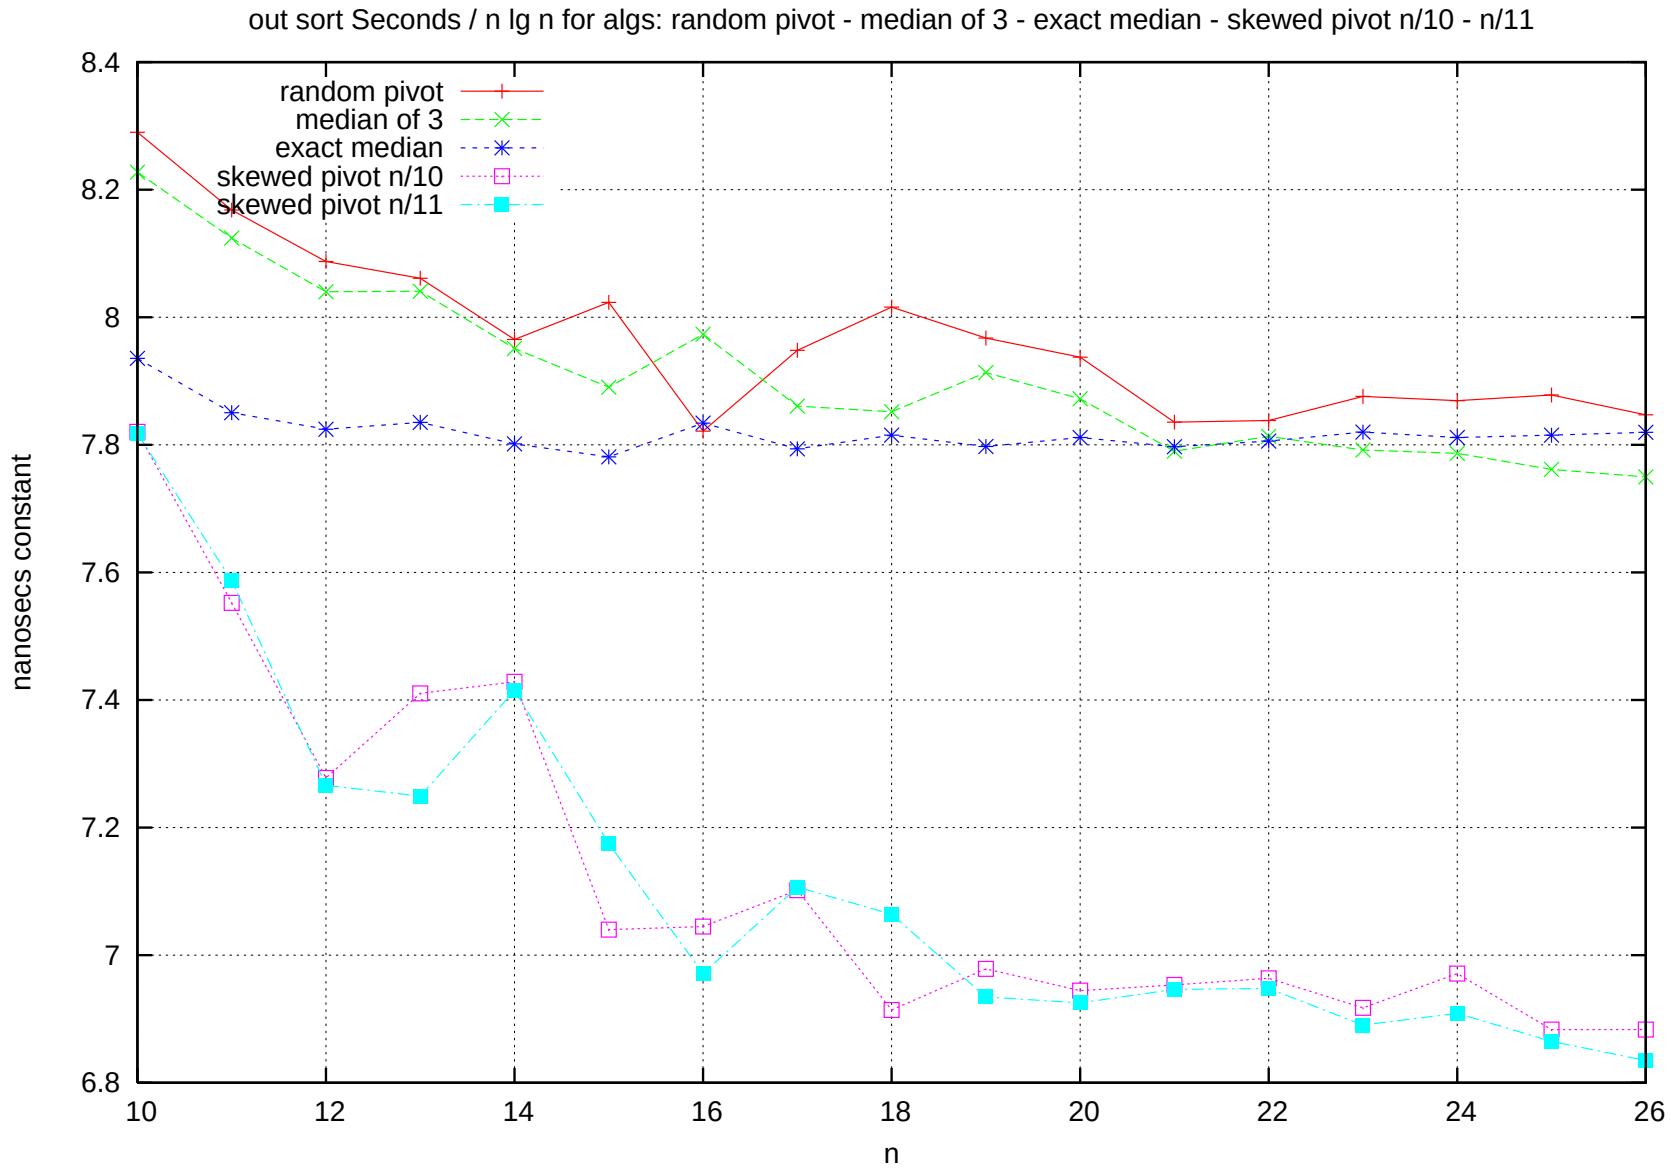
Practice

3GHz Pentium 4 Prescott, g++

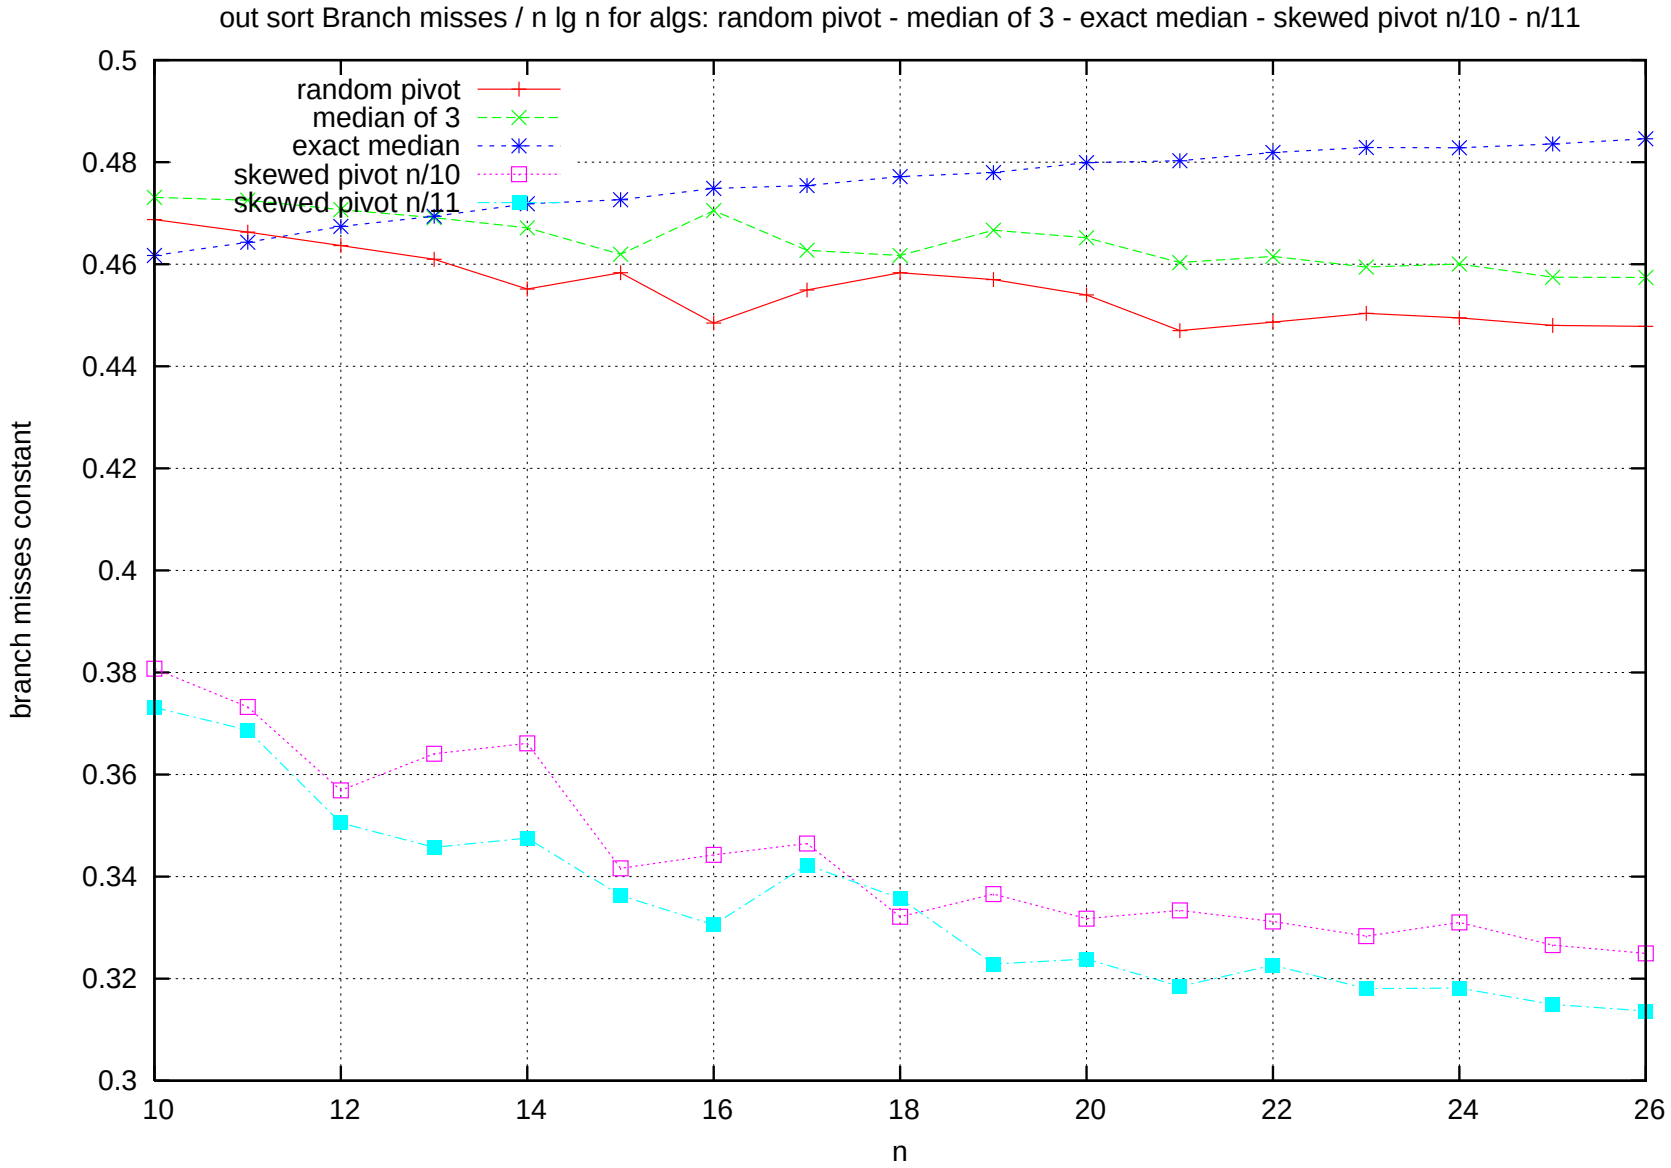
Picking Pivots Painstakingly — Instructions



Picking Pivots Painstakingly — Time



Picking Pivots Painstakingly — Branch Misses



Can We Do Better? Previous Work

Integer Keys

+ Can be $2-3$ times faster than quicksort
– Naive ones are cache inefficient and slower than quicksort
– Simple ones are distribution dependent.

Cache efficient sorting

k-ary merge sort

[Nyberg et al. 94, Arge et al. 04, Ranade et al. 00, Brodal et al. 04]

+ Faktor $\log k$ less cache faults
– Only ≈ 20 % speedup, and only for laaarge inputs

Sample Sort

Function sampleSort$(e = \langle e_1, \ldots, e_n \rangle, k)$

if n/k is "small" **then return** smallSort(e)

let $S = \langle S_1, \ldots, S_{ak-1} \rangle$ denote a random sample of e

sort S

$\langle s_0, s_1, s_2, \ldots, s_{k-1}, s_k \rangle :=$

$\langle -\infty, S_a, S_{2a}, \ldots, S_{(k-1)a}, \infty \rangle$

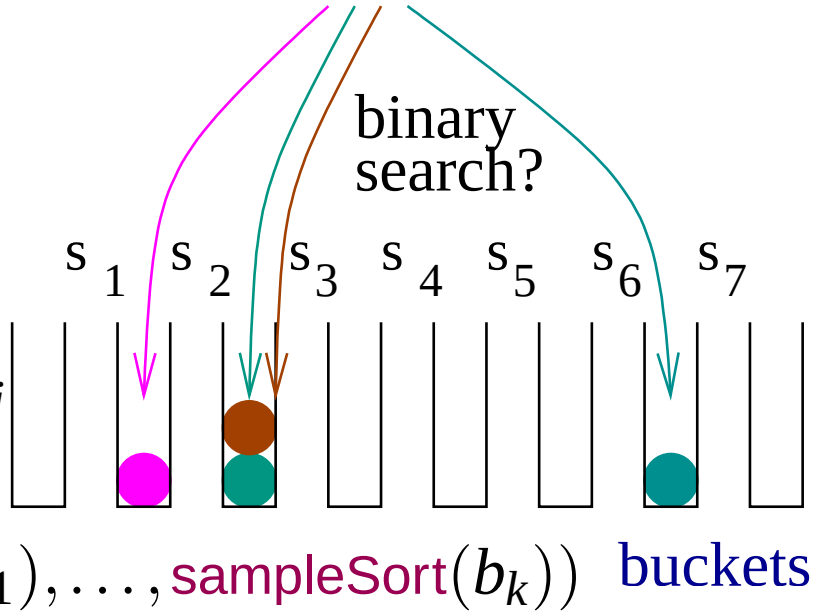
for $i := 1$ **to** n **do**

find $j \in \{1, \ldots, k\}$

such that $s_{j-1} < e_i \leq s_j$

place e_i in bucket b_j

return concatenate(sampleSort$(b_1), \ldots,$ sampleSort(b_k))



Why Sample Sort?

- traditionally: parallelizable on coarse grained machines
- \+ Cache efficient $\approx$ merge sort
- – Binary search not much faster than merging
- – complicated memory management

Super Scalar Sample Sort

- Binary search $\longrightarrow$ implicit search tree
- Eliminate all conditional branches
- $\rightsquigarrow$ Exploit instruction parallelism
- $\rightsquigarrow$ Cache efficiency comes to bear
- “steal” memory management from radix sort

Classifying Elements

$t := \langle s_{k/2}, s_{k/4}, s_{3k/4}, s_{k/8}, s_{3k/8}, s_{5k/8}, s_{7k/8}, \ldots \rangle$

for $i := 1$ **to** n **do**

$j := 1$

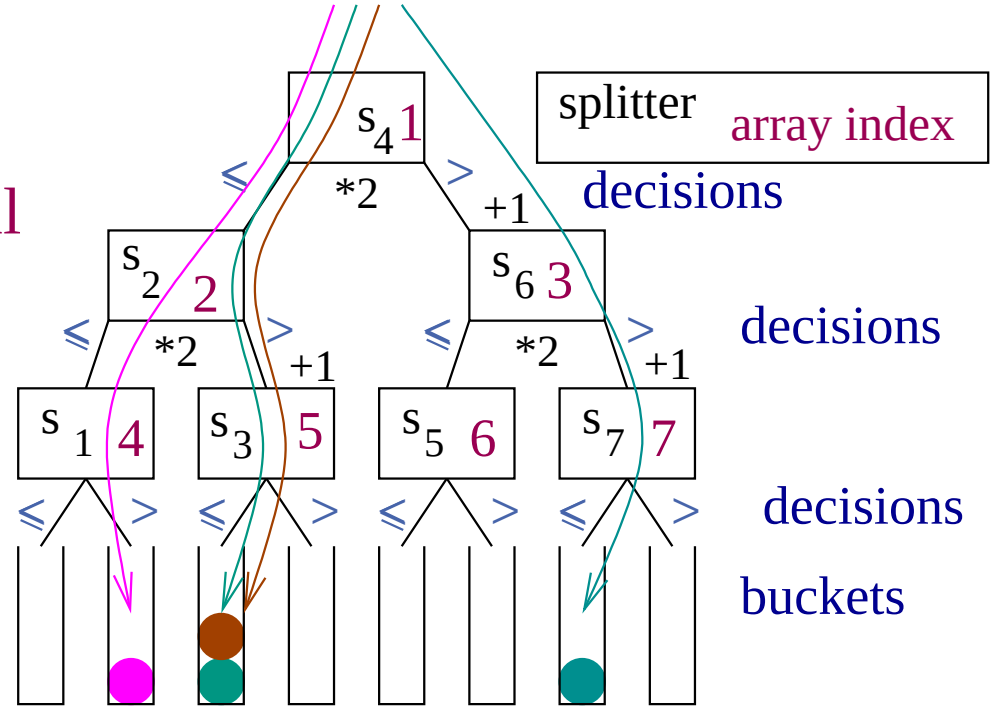
repeat $\log k$ times // unroll

$j := 2j + (a_i > t_j)$

$j := j - k + 1$

$|b_j|{+}{+}$

oracle$[i] := j$ // oracle



Now the compiler should:

- use predicated instructions
- interleave for-loop iterations (unrolling ∨ software pipelining)

```
template <class T>
void findOraclesAndCount(const T* const a,
    const int n, const int k, const T* const s,
    Oracle* const oracle, int* const bucket) {
{ for (int i = 0;  i < n;  i++)
    int j = 1;
    while (j < k) {
      j = j*2 + (a[i] > s[j]);
    }
    int b = j-k;
    bucket[b]++;
    oracle[i] = b;
  }
}
```

Predication

Hardware mechanism that allows instructions to be conditionally executed

- Boolean predicate registers (1–64) hold condition codes
- predicate registers p are additional inputs of predicated instructions I
- At runtime, I is executed if and only if p is true
- \+ Avoids branch misprediction penalty
- \+ More flexible instruction scheduling
- – Switched off instructions still take time
- – Longer opcodes
- – Complicated hardware design

Example (IA-64)

Translation of: if (r1 > 2) r3 := r3 + 4

With a conditional branch:

```
      cmp.gt p6,p7=r1,r2
(p7)  br.cond .label
      add r3=4,r3
.label:
                    (...)
```

Via predication:

```
      cmp.gt p6,p7=r1,r2
(p6)  add r3=4,r3
```

Other Current Architectures:

Conditional moves only

Unrolling ($k = 16$)

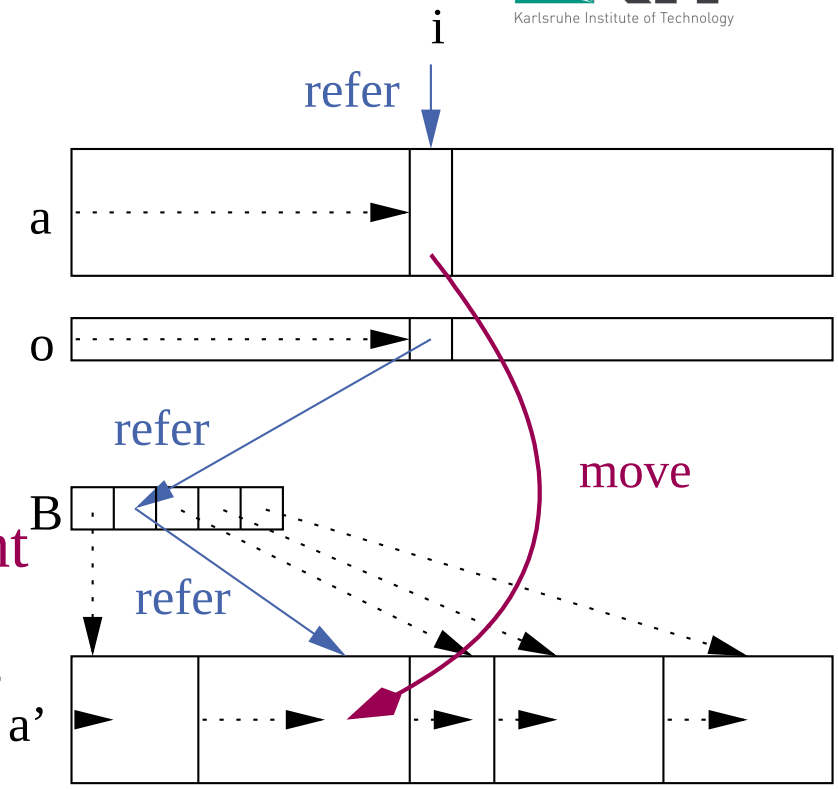
```
template <class T>
void findOraclesAndCountUnrolled([...]){
  for (int i = 0;  i < n;  i++)
    int j = 1;
    j = j*2 + (a[i] > s[j]);
    j = j*2 + (a[i] > s[j]);
    j = j*2 + (a[i] > s[j]);
    j = j*2 + (a[i] > s[j]);
    int b = j-k;
    bucket[b]++;
    oracle[i] = b;
} }
```

More Unrolling $k = 16$, n even

```
template <class T>
void findOraclesAndCountUnrolled2([...]){
   for (int i = n & 1;  i < n;  i+=2) {\
      int j0 = 1;                int j1 = 1;
      T  ai0 = a[i];             T ai1  = a[i+1];
      j0=j0*2+(ai0>s[j0]);  j1=j1*2+(ai1>s[j1]);
      j0=j0*2+(ai0>s[j0]);  j1=j1*2+(ai1>s[j1]);
      j0=j0*2+(ai0>s[j0]);  j1=j1*2+(ai1>s[j1]);
      j0=j0*2+(ai0>s[j0]);  j1=j1*2+(ai1>s[j1]);
      int b0 = j0-k;             int b1 = j1-k;
      bucket[b0]++;              bucket[b1]++;
      oracle[i] = b0;            oracle[i+1] = b1;
} }
```

Distributing Elements

for $i := 1$ **to** n **do** $a'_{B[\text{oracle}[i]]++} := a_i$



Why Oracles?

- simplifies memory management
- no overflow tests or re-copying
- simplifies software pipelining
- separates computation and memory access aspects
- small (n bytes)
- sequential, predictable memory access
- can be hidden using prefetching / write buffering

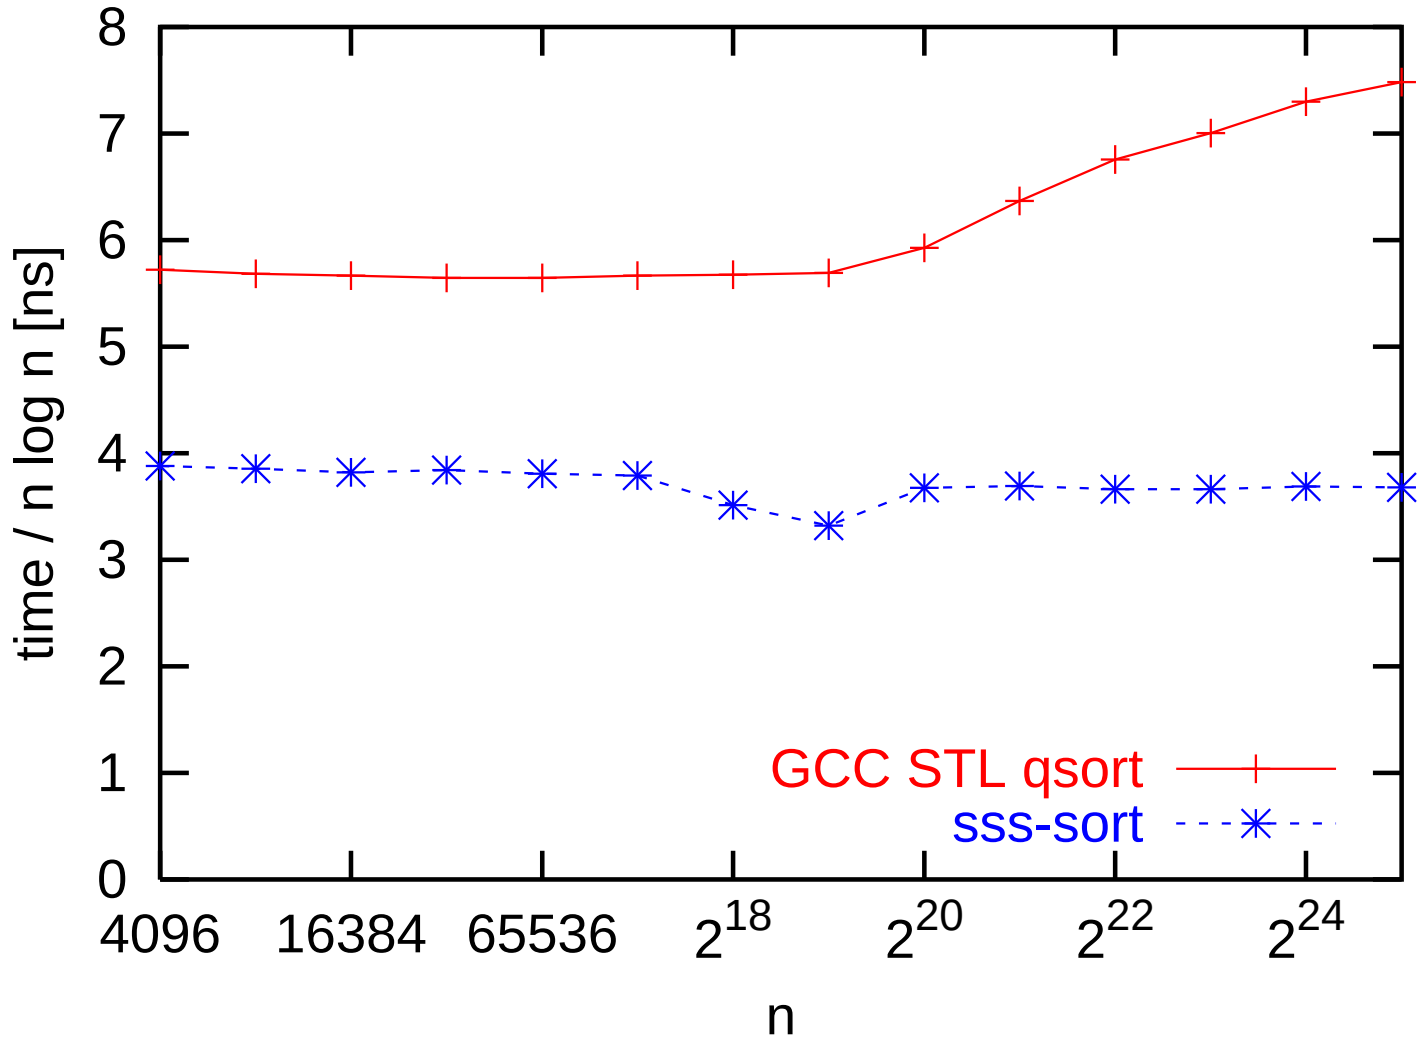
Distributing Elements

```
template <class T> void distribute(
  const T* const a0, T* const a1,
  const int n, const int k,
  const Oracle* const oracle, int* const bucket)
{ for (int i = 0, sum = 0;  i <= k;  i++) {
    int t = bucket[i];  bucket[i] = sum;  sum += t;
  }
  for (int i = 0; i < n;  i++) {
    a1[bucket[oracle[i]]++] = a0[i];
  }
}
```

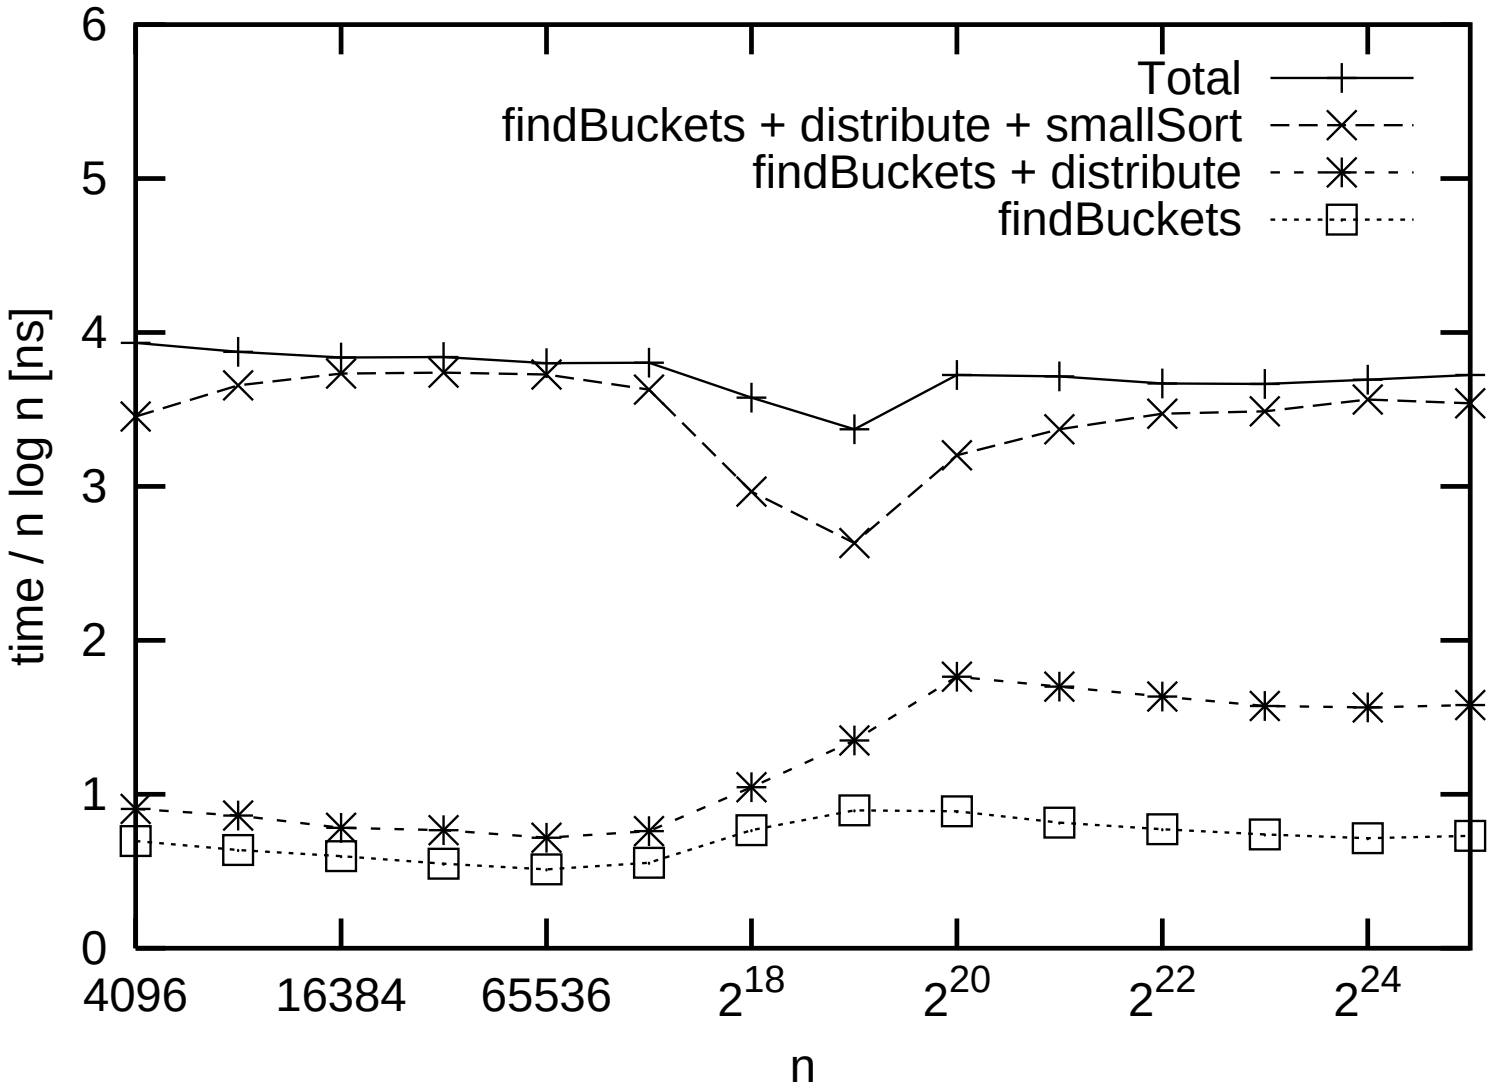
Experiments: 1.4 GHz Itanium 2

- `restrict` keyword from ANSI/ISO C99 to indicate nonaliasing
- Intel's C++ compiler v8.0 uses predicated instructions automatically
- Profiling gives 9% speedup
- $k = 256$ splitters
- Use `stl:sort` from g++ ($n \leq 1000$)!
- insertion sort for $n \leq 100$
- Random 32 bit integers in $[0, 10^9]$

Comparison with Quicksort



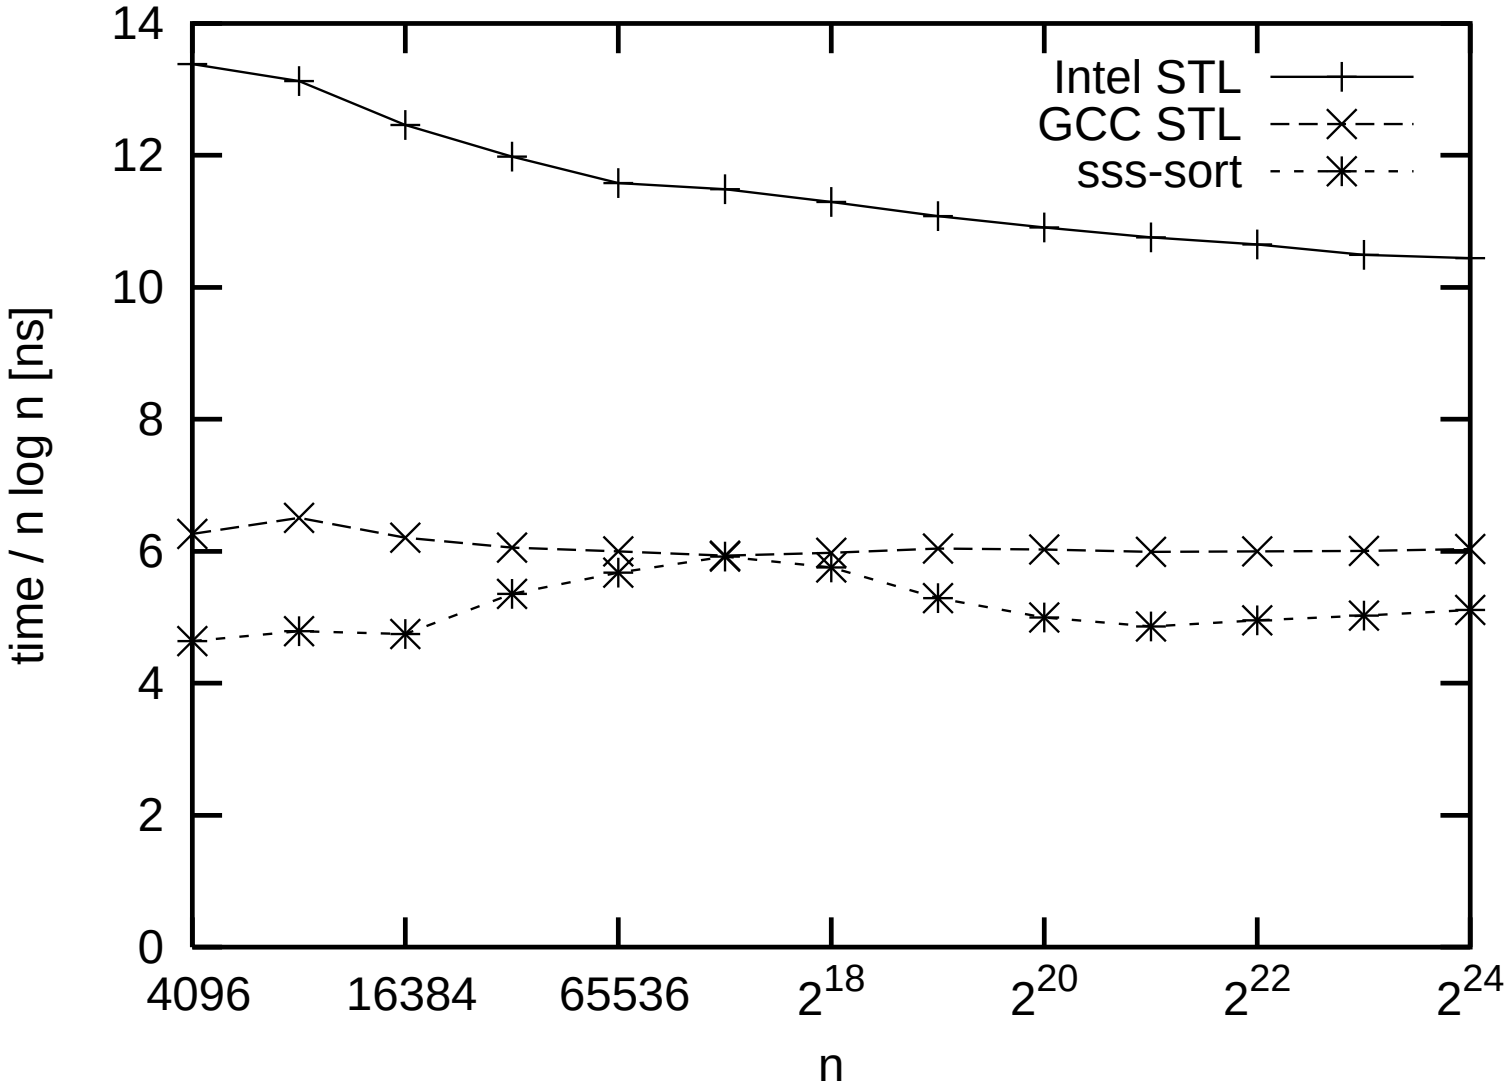
Breakdown of Execution Time



A More Detailed View

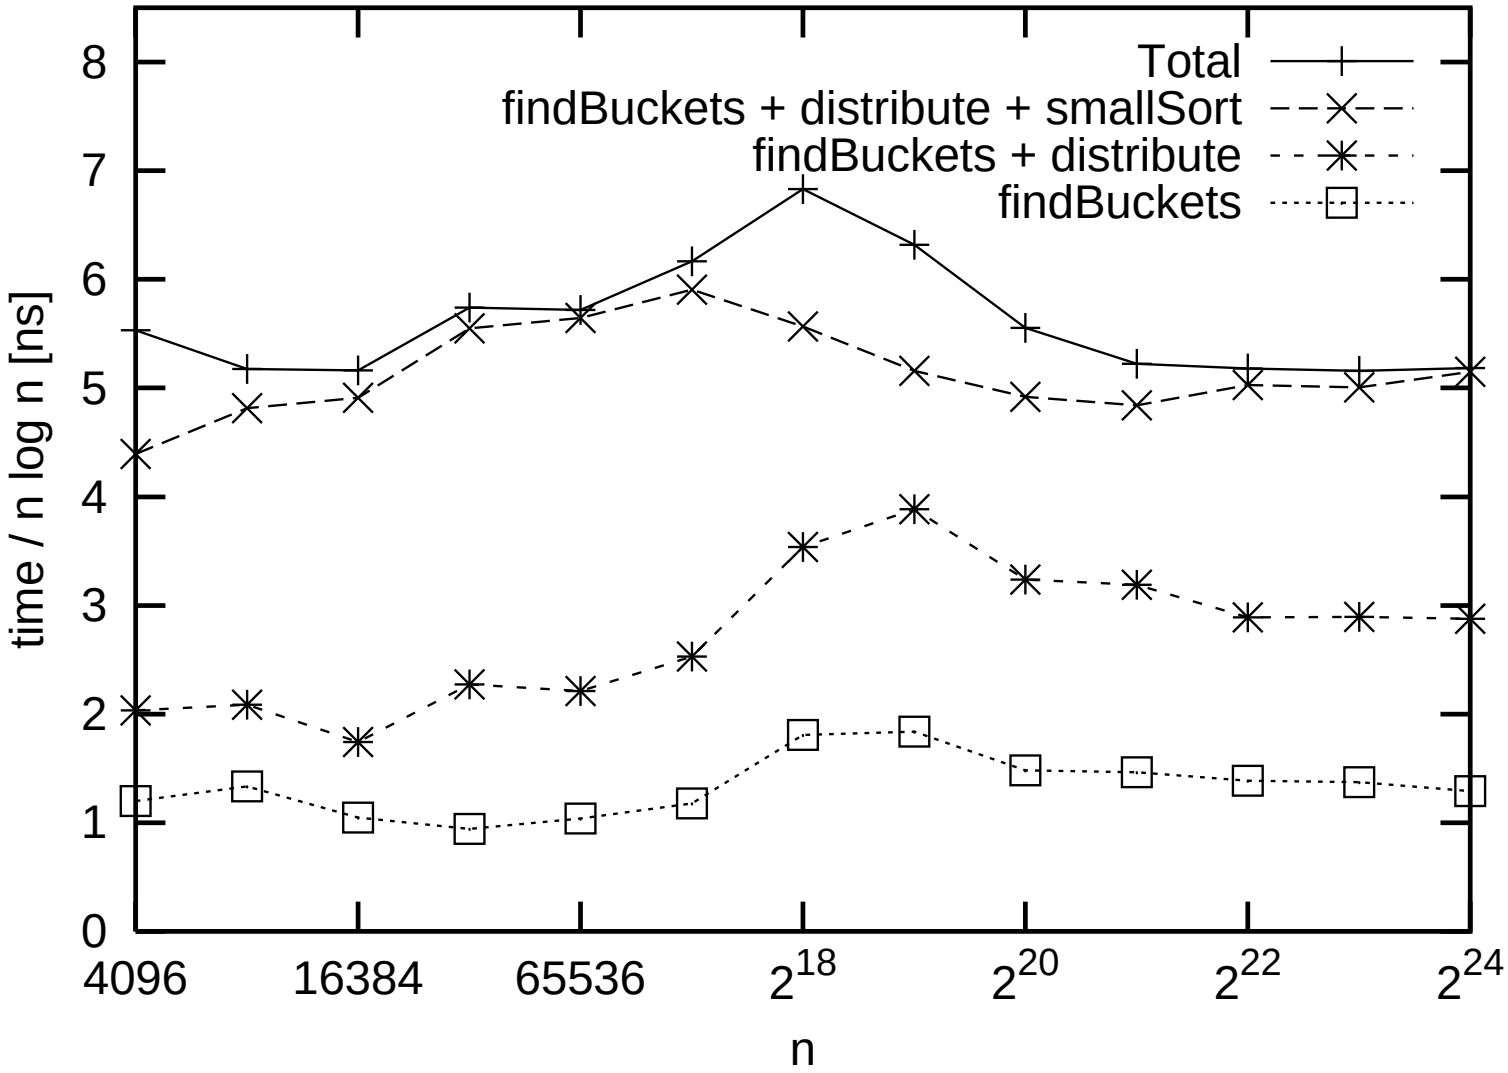
	instr.	cycles	dynamic IPC small n	dynamic IPC $n = 2^{25}$
findBuckets, $1\times$ outer loop	63	11	5.4	4.5
distribute, one element	14	4	3.5	0.8

Comparison with Quicksort Pentium 4



Problems: few registers, one condition code only, compiler needs “help”

Breakdown of Execution Time Pentium 4



Analysis

	mem. acc.	branches	data dep.	I/Os	registers	instructions
k-way distribution:						
sss-sort	$n \log k$	$\mathcal{O}(1)$	$\mathcal{O}(n)$	$3.5n/B$	$3\times$unroll	$\mathcal{O}(\log k)$
quicksort $\log k$ lvls.	$2n \log k$	$n \log k$	$\mathcal{O}(n \log k)$	$2\frac{n}{B} \log k$	4	$\mathcal{O}(1)$
k-way merging:						
memory	$n \log k$	$n \log k$	$\mathcal{O}(n \log k)$	$2n/B$	7	$\mathcal{O}(\log k)$
register	$2n$	$n \log k$	$\mathcal{O}(n \log k)$	$2n/B$	k	$\mathcal{O}(k)$
funnel $k'^{\log_{k'} k}$	$2n \log_{k'} k$	$n \log k$	$\mathcal{O}(n \log k)$	$2n/B$	$2k'+2$	$\mathcal{O}(k')$

Conclusions

- sss-sort up to twice as fast as quicksort on Itanium
- comparisons $\neq$ conditional branches
- algorithm analysis is not just instructions and caches

New result: GPU-Sample-Sort is best comparison based sorting algorithm on graphic hardware
[Leischner/Osipov/Sanders 2009]

Criticism I

Why only random keys?

Answer I

Sample sort hardly depends on input distribution

Criticism I´

What if there are many equal keys?

They all end up in the same bucket

Answer I´

Its not a bug its a feature:

$s_i = s_{i+1} = \cdots = s_j$ indicates a frequent key!

Set $s_i := \max\{x \in Key : x < s_i\}$,

(optional: drop $s_{i+2}, \ldots s_j$)

Now bucket $i+1$ need not be sorted!

todo: implement

Criticism II

Quicksort is inplace

Answer II

Use hybrid List-Array Representation of sequences

needs $\mathcal{O}\left(\sqrt{kn}\right)$ extra space for k-way sample sort

Criticism II´

But I WANT Arrays for input and output

Answer II´

Inplace Konversion

input: easy

output: tricky. Exercise: develop rough idea. Hint: permute blocks. Each permutation consists of a product of cyclic permutations. An inplace cyclic permuation is easy.

Future Work

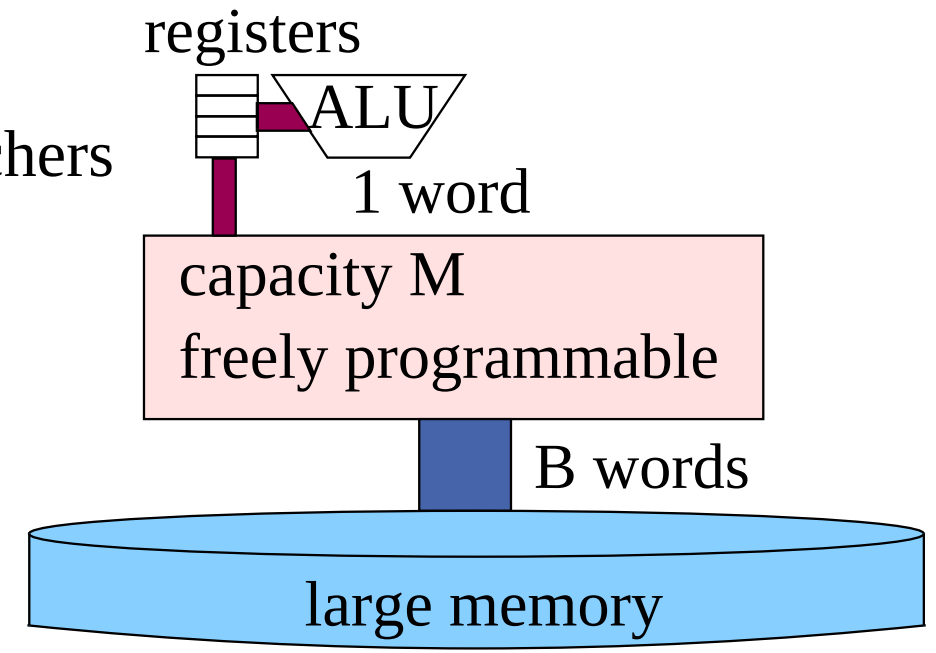
- high level fine-tuning, e.g., clever choice of k
- modern architectures
- almost in-place implementation
- multilevel cache-aware or cache-oblivious generalization (oracles help)

Externes Sortieren

n: Eingabegröße

M: Größe des schnellen Speichers

B: Blockgröße



Procedure externalMerge$(a, b, c$:File **of** Element$)$

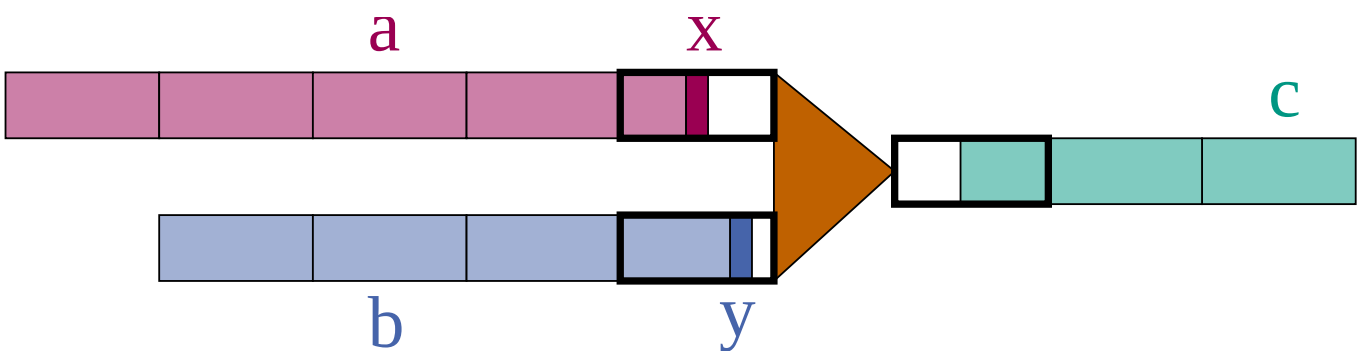
x := a.readElement // Assume emptyFile.readElement$= \infty$

y := b.readElement

for $j := 1$ **to** $|a| + |b|$ **do**

if $x \leq y$ **then** c.writeElement(x); x := a.readElement

else c.writeElement(y); y := b.readElement



Externes (binäres) Mischen – I/O-Analyse

Datei a lesen: $\lceil |a|/B \rceil \leq |a|/B + 1$.

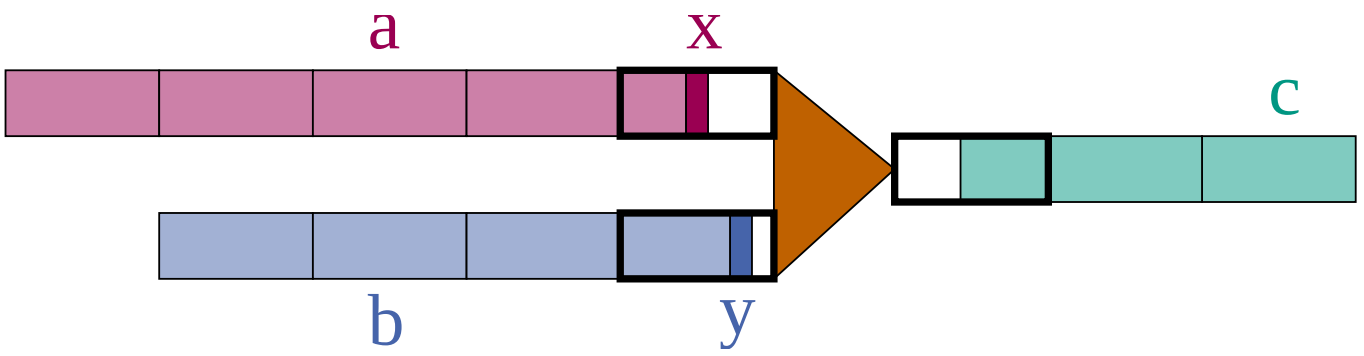
Datei b lesen: $\lceil |b|/B \rceil \leq |b|/B + 1$.

Datei c schreiben: $\lceil (|a| + |b|)/B \rceil \leq (|a| + |b|)/B + 1$.

Insgesamt:

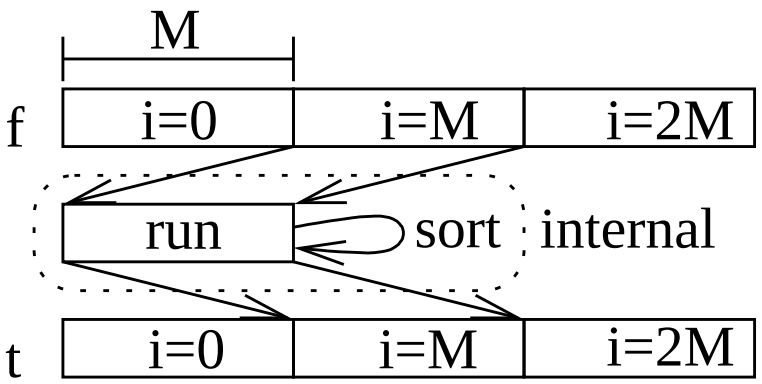
$$\leq 3 + 2\frac{|a| + |b|}{B} \approx 2\frac{|a| + |b|}{B}$$

Bedingung: Wir brauchen 3 Pufferblöcke, d.h., $M > 3B$.



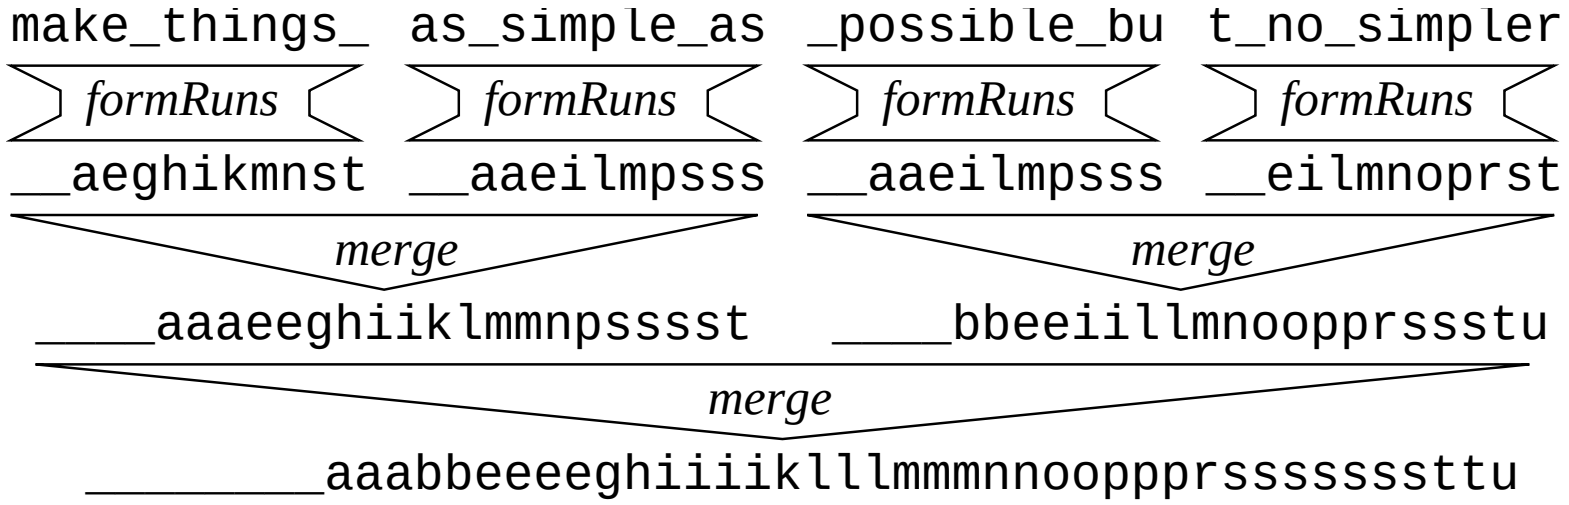
Run Formation

Sortiere Eingabeportionen der Größe M



I/Os: $\approx 2\frac{n}{B}$

Sortieren durch Externes Binäres Mischen



Procedure externalBinaryMergeSort // I/Os: $\approx$

run formation // $2n/B$

while more than one run left **do** // $\lceil \log \frac{n}{M} \rceil \times$

merge pairs of runs // 2n/B

output remaining run // $\sum : 2\frac{n}{B}\left(1 + \left\lceil \log \frac{n}{M} \right\rceil\right)$

Zahlenbeispiel: PC 2007

$n = 2^{38}$ Byte

$M = 2^{31}$ Byte

$B = 2^{20}$ Byte

I/O braucht 2^{-6} s

Zeit: $2\frac{n}{B}\left(1+\left\lceil \log \frac{n}{M} \right\rceil\right) = 2 \cdot 2^{18} \cdot (1+7) \cdot 2^{-6}$ s $= 2^{16}$ s≈ 18 h

Idee: 8 Durchläufe $\rightsquigarrow$ 2 Durchläufe

Zahlenbeispiel: PC 2007 $\rightarrow$ 2009

$n = 2^{38\rightarrow 39}$ Byte

$M = 2^{31\rightarrow 32}$ Byte

$B = 2^{20\rightarrow 21}$ Byte

I/O braucht 2^{-6} s

Zeit: $2\frac{n}{B}\left(1+\left\lceil \log\frac{n}{M}\right\rceil\right) = 2\cdot 2^{18}\cdot(1+7)\cdot 2^{-6}\text{ s} = 2^{16}\text{ s} \approx 18\text{ h}$

Mehrwegemischen

Procedure multiwayMerge$(a_1, \ldots, a_k, c$:File **of** Element$)$

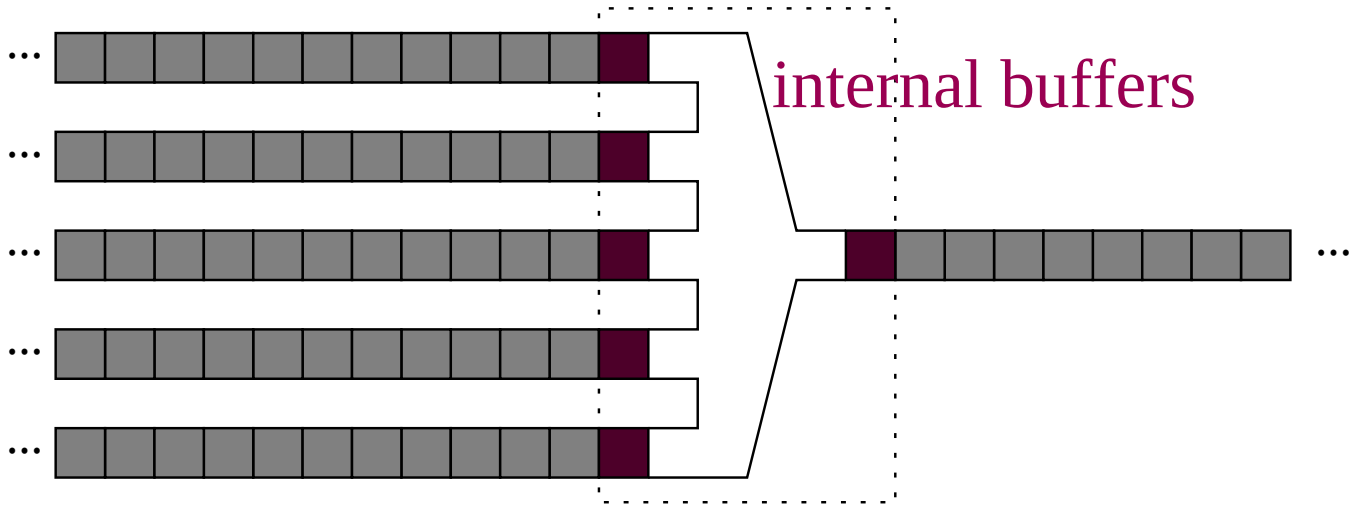
for $i := 1$ **to** k **do** $x_i := a_i$.readElement

for $j := 1$ **to** $\sum_{i=1}^{k} |a_i|$ **do**

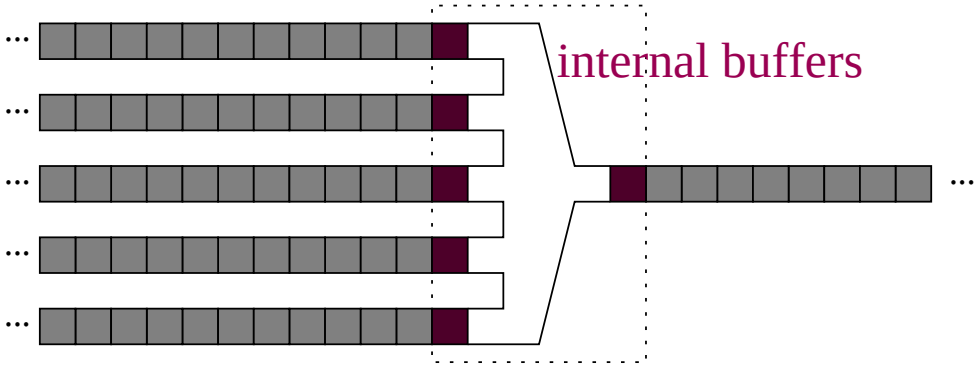
find $i \in 1..k$ that minimizes x_i// no I/Os!, $\mathcal{O}(\log k)$ time

c.writeElement(x_i)

$x_i := a_i$.readElement



Mehrwegemischen – Analyse



I/Os: Datei a_i lesen: $\approx |a_i|/B$.

Datei c schreiben: $\approx \sum_{i=1}^{k} |a_i|/B$

Insgesamt:

$$\leq\approx 2\frac{\sum_{i=1}^{k} |a_i|}{B}$$

Bedingung: Wir brauchen k Pufferblöcke, d.h., $k < M/B$.

Interne Arbeit: (benutze Prioritätsliste !)

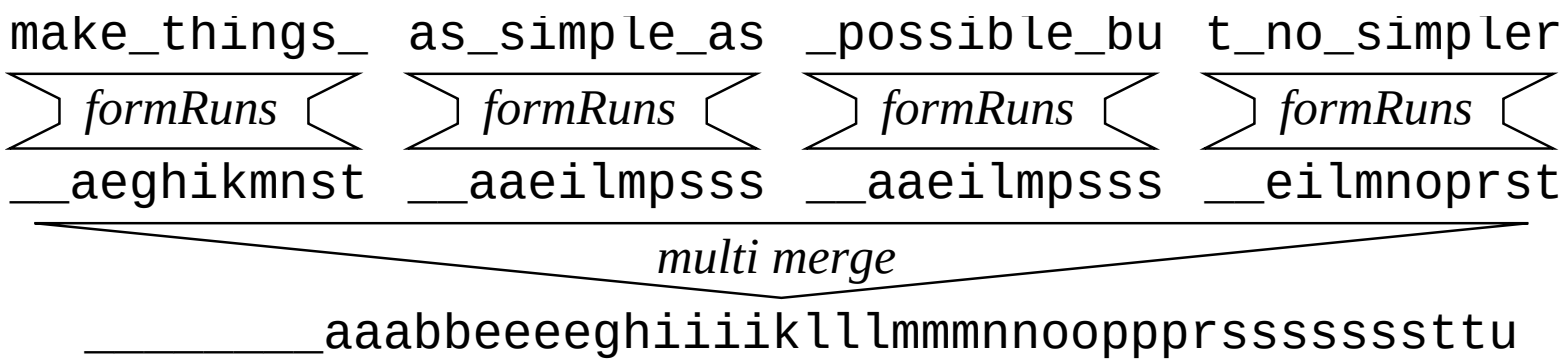
$$\mathcal{O}\left(\log k \sum_{i=1}^{k} |a_i|\right)$$

Sortieren durch Mehrwege-Mischen

- Sortiere $\lceil n/M \rceil$ runs mit je M Elementen — $2n/B$ I/Os
- Mische jeweils M/B runs — $2n/B$ I/Os
- bis nur noch ein run übrig ist — $\times \left\lceil \log_{M/B} \frac{n}{M} \right\rceil$ Mischphasen

Insgesamt

$$\text{sort}(n) := \frac{2n}{B}\left(1 + \left\lceil \log_{M/B} \frac{n}{M} \right\rceil\right) \text{ I/Os}$$



Sortieren durch Mehrwege-Mischen

Interne Arbeit:

$$\mathcal{O}\left(\overbrace{n\log M}^{\text{run formation}} + \underbrace{n\log\frac{M}{B}}_{\text{PQ access per phase}} \overbrace{\left\lceil\log_{M/B}\frac{n}{M}\right\rceil}^{\text{phases}}\right) = \mathcal{O}(n\log n)$$

Mehr als eine Mischphase?:

Nicht für Hierarchie Hauptspeicher, Festplatte.

Grund $\overbrace{\frac{M}{B}}^{>1000} > \overbrace{\frac{\text{RAM Euro/bit}}{\text{Platte Euro/bit}}}^{<1000}$

11-2010: $\frac{8GB}{4MB} = 2048 > \frac{50/4GB}{80/2TB} = 320$

Mehr zu externem Sortieren

Untere Schranke $\approx \frac{2^{(?)}n}{B}\left(1+\left\lceil \log_{M/B}\frac{n}{M}\right\rceil\right)$ I/Os

[Aggarwal Vitter 1988]

Obere Schranke $\approx \frac{2n}{DB}\left(1+\left\lceil \log_{M/B}\frac{n}{M}\right\rceil\right)$ I/Os (erwartet)

für D parallele Platten

[Hutchinson Sanders Vitter 2005, Dementiev Sanders2003]

Offene Frage: deterministisch?

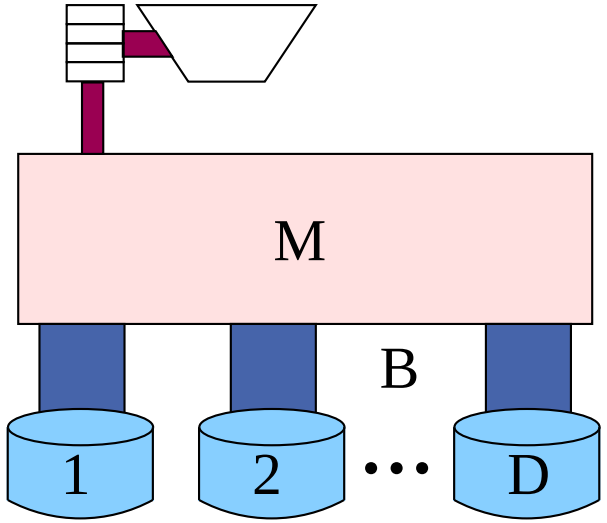
Sorting with Parallel Disks

I/O Step := Access to a single physical block per disk

Theory: Balance Sort [Nodine Vitter 93].

Deterministic, complex

asymptotically optimal  $\mathcal{O}(\cdot)$



independent disks

[Vitter Shriver 94]

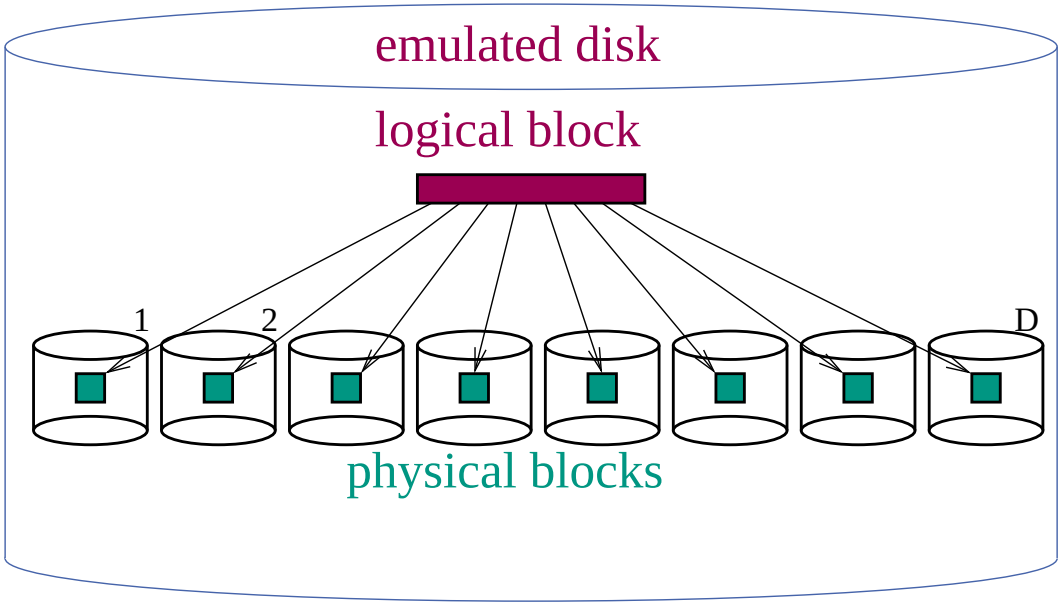
Multiway merging

"Usually" factor 10? less I/Os.

Not asymptotically optimal. 42%

Basic Approach: Improve Multiway Merging

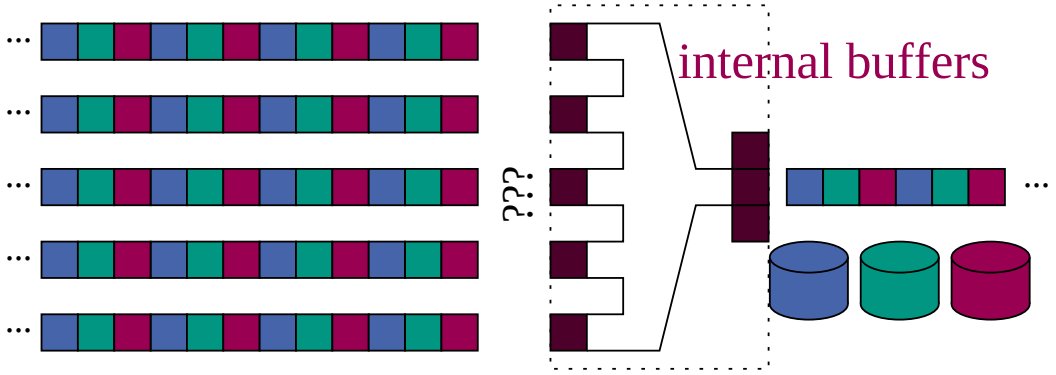
Striping



That takes care of run formation

and writing the output

But what about merging?



Naive Striping

Run single disk merge-sort on striped logical disk:

$$\frac{2n}{DB}\left(1+\left\lceil \log_{M/DB}\frac{n}{M}\right\rceil\right) \text{ I/Os}$$

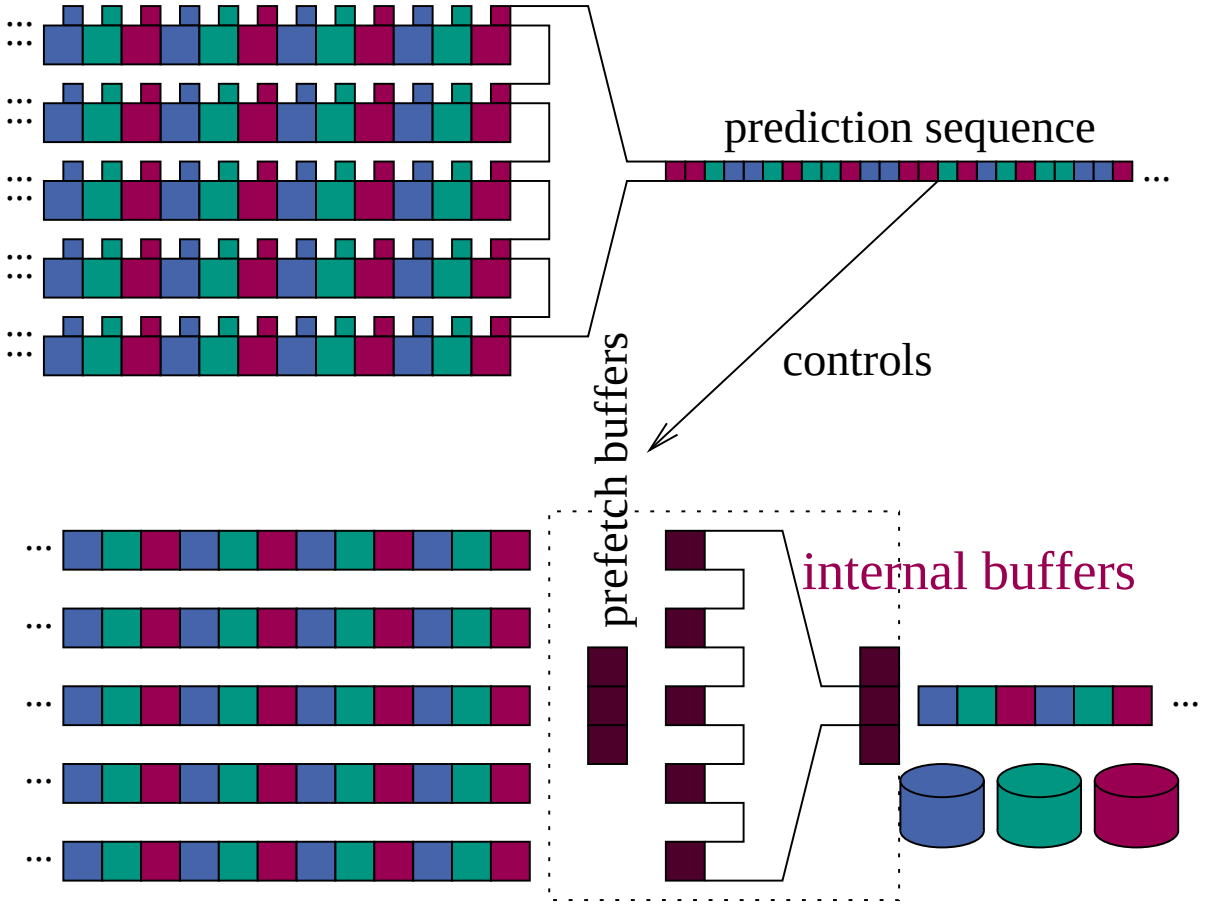
Theory: $\Theta(\log M/B)$ worse when $D \approx M/B$

Practice: $2 \rightarrow 3$ passes in some cases

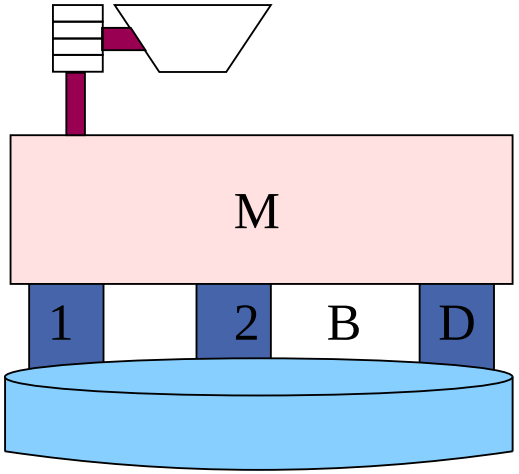
Prediction

[Folklore, Knuth]
Smallest Element
of each block
triggers fetch.

Prefetch buffers
allow parallel access
of next blocks

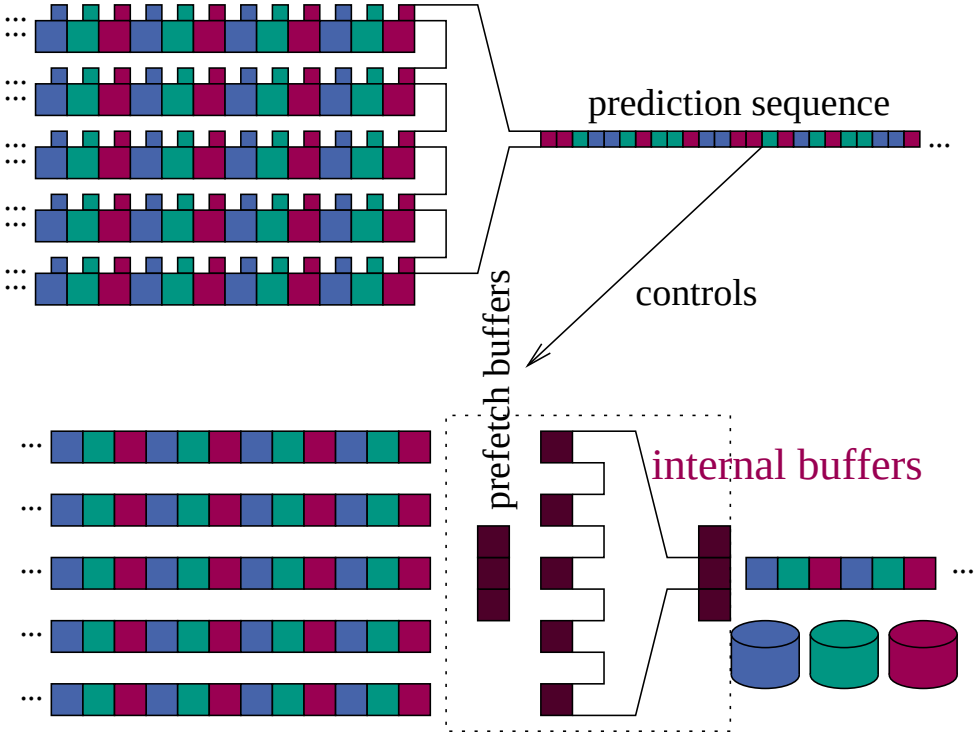


Warmup: Multihead Model



Multihead Model

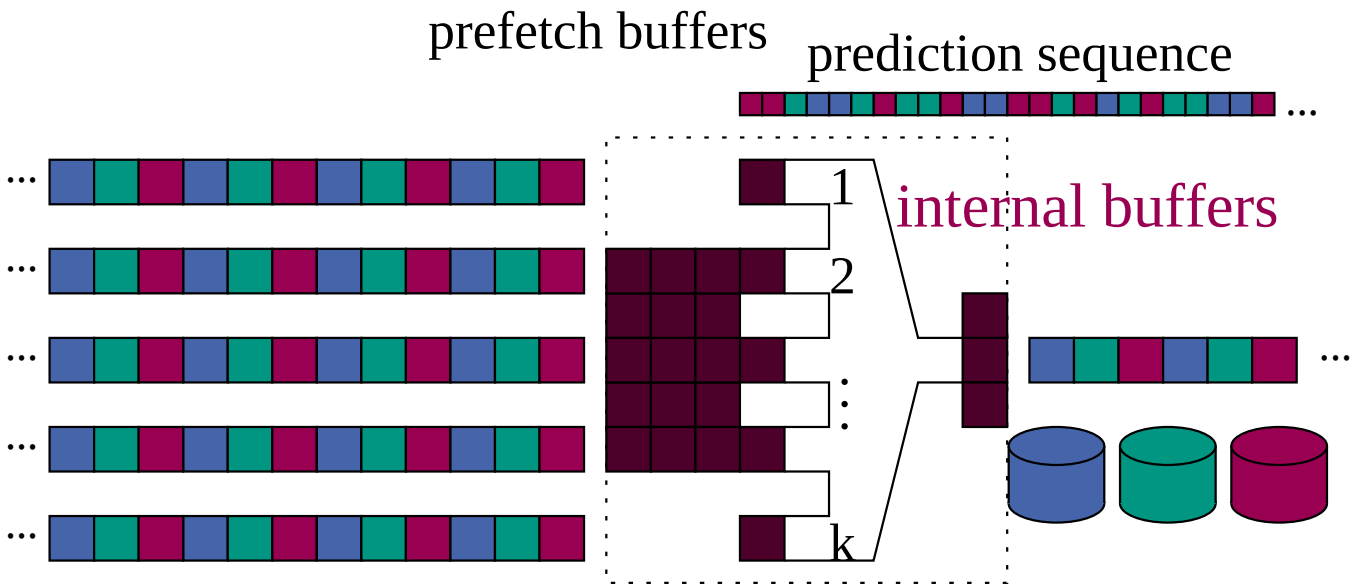
[Aggarwal Vitter 88]



D prefetch buffers yield an optimal algorithm

$$\text{sort}(n) := \frac{2n}{DB}\left(1+\left\lceil \log_{M/B}\frac{n}{M}\right\rceil\right) \text{ I/Os}$$

Bigger Prefetch Buffer



$Dk \rightsquigarrow$ good deterministic performance

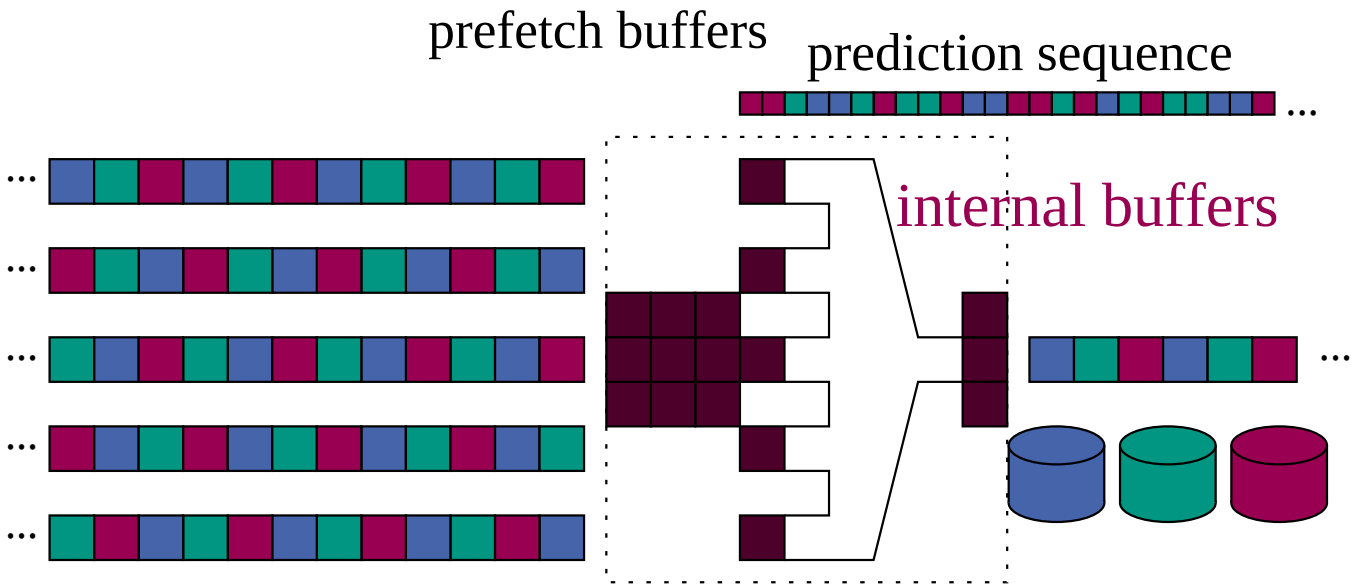
$\mathcal{O}(D)$ would yield an optimal algorithm.

Possible?

Randomized Cycling

[Vitter Hutchinson 01]

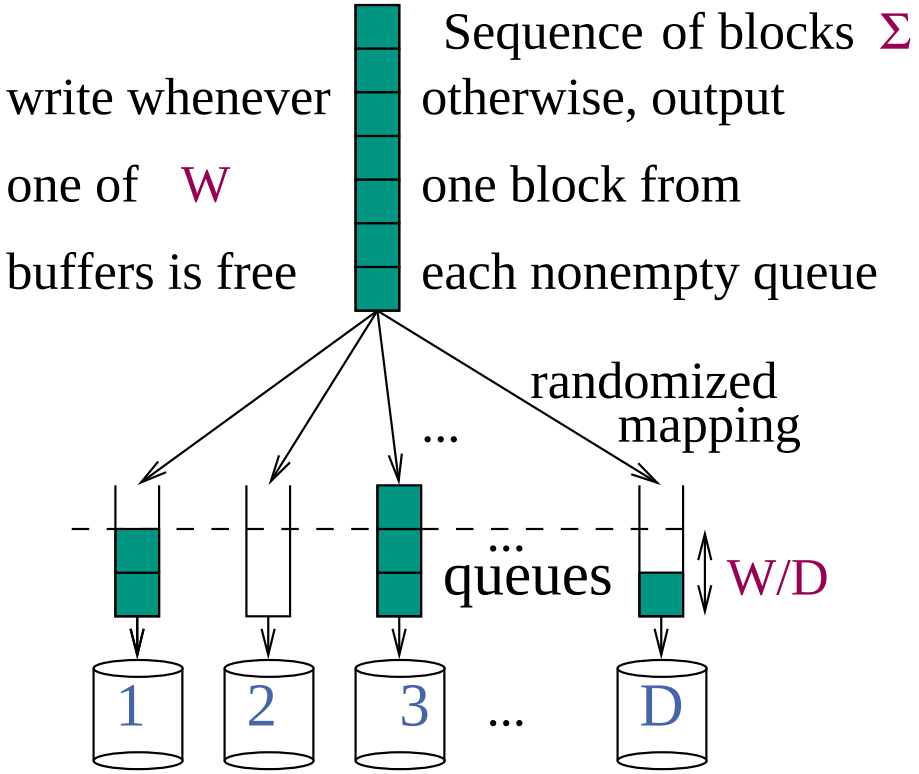
Block i of stripe j goes to disk $\pi_j(i)$ for a rand. permutation π_j



Good for naive prefetching and $\Omega(D \log D)$ buffers

Buffered Writing

[S-Egner-Korst SODA00, Hutchinson-S-Vitter ESA 01]



Theorem:
Buffered Writing
is optimal
...
But
how good is optimal?

Theorem: Rand. cycling achieves efficiency $1 - \mathcal{O}(D/W)$.

Analysis: negative association of random variables,
application of queueing theory to a "throttled" Alg.

Optimal Offline Prefetching

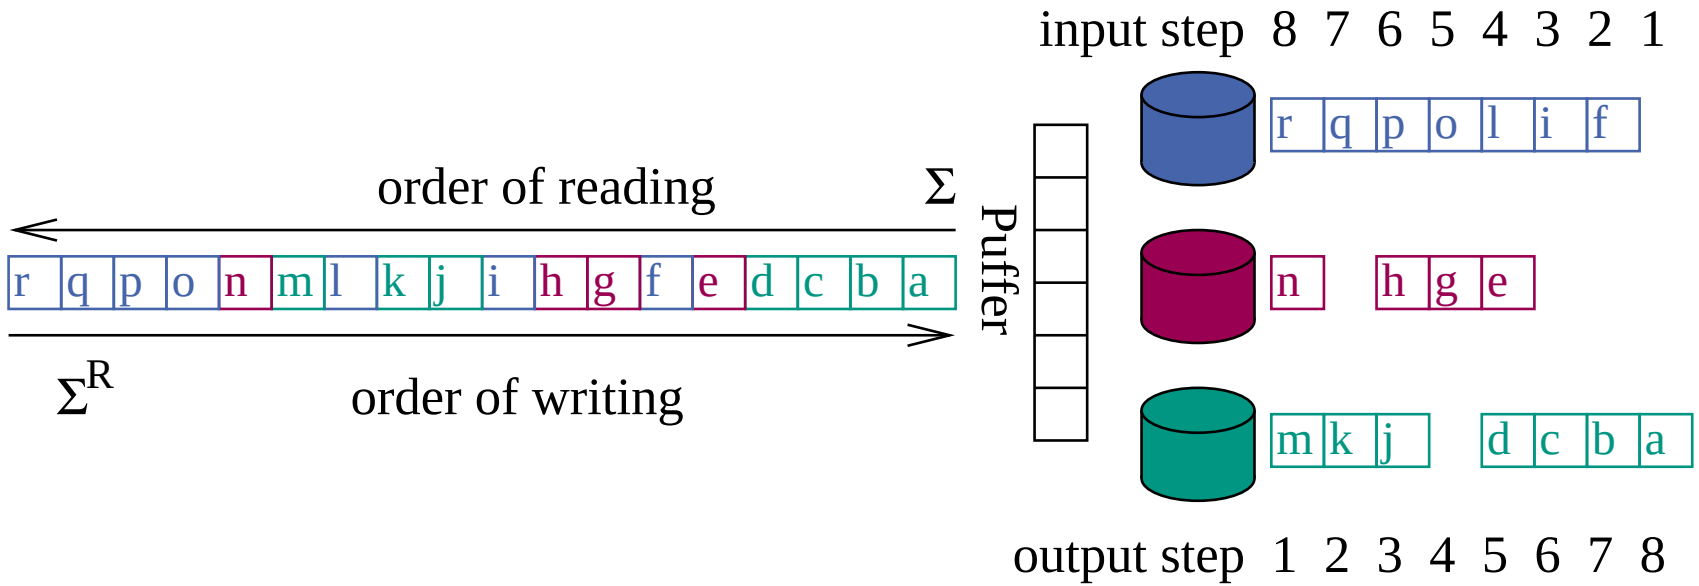
Theorem:

For buffer size W:

$\exists$ (offline) prefetching schedule for Σ with T input steps

$\Leftrightarrow$

$\exists$ (online) write schedule for Σ^R with T output steps



Optimal Offline Prefetching

Theorem:

For buffer size W:

Synthesis

Multiway merging

+ prediction [60s Folklore]

+optimal (randomized) writing [S-Egner-Korst SODA 2000]

+randomized cycling [Vitter Hutchinson 2001]

+optimal prefetching [Hutchinson-S-Vitter ESA 2002]

$\rightsquigarrow (1+o(1))\cdot \text{sort}(n)$ I/Os

$\rightsquigarrow$"answers" question in [Knuth 98];

difficulty 48 on a 1..50 scale.

We are not done yet!

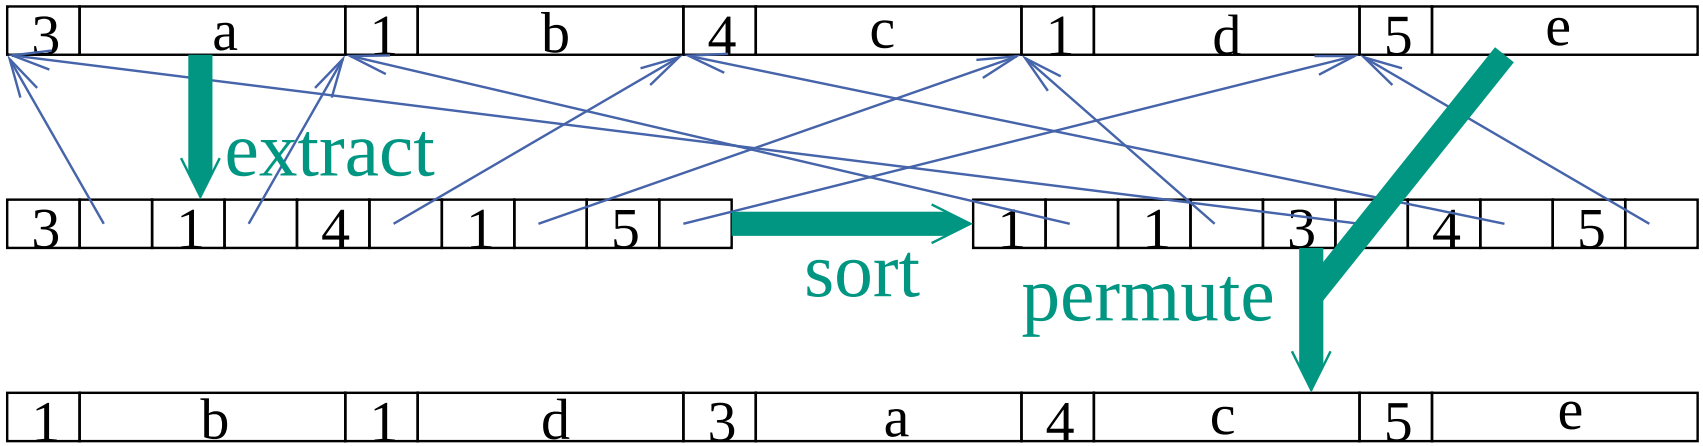
- Internal work
- Overlapping I/O and computation
- Reasonable hardware
- Interfacing with the Operating System
- Parameter Tuning
- Software engineering
- Pipelining

Key Sorting

The I/O bandwidth of our machine is about $1/3$ of its main memory bandwidth

$\rightsquigarrow$ If key size $\ll$ element size

sort key pointer pairs to save memory bandwidth during run formation



Tournament Trees for Multiway Merging

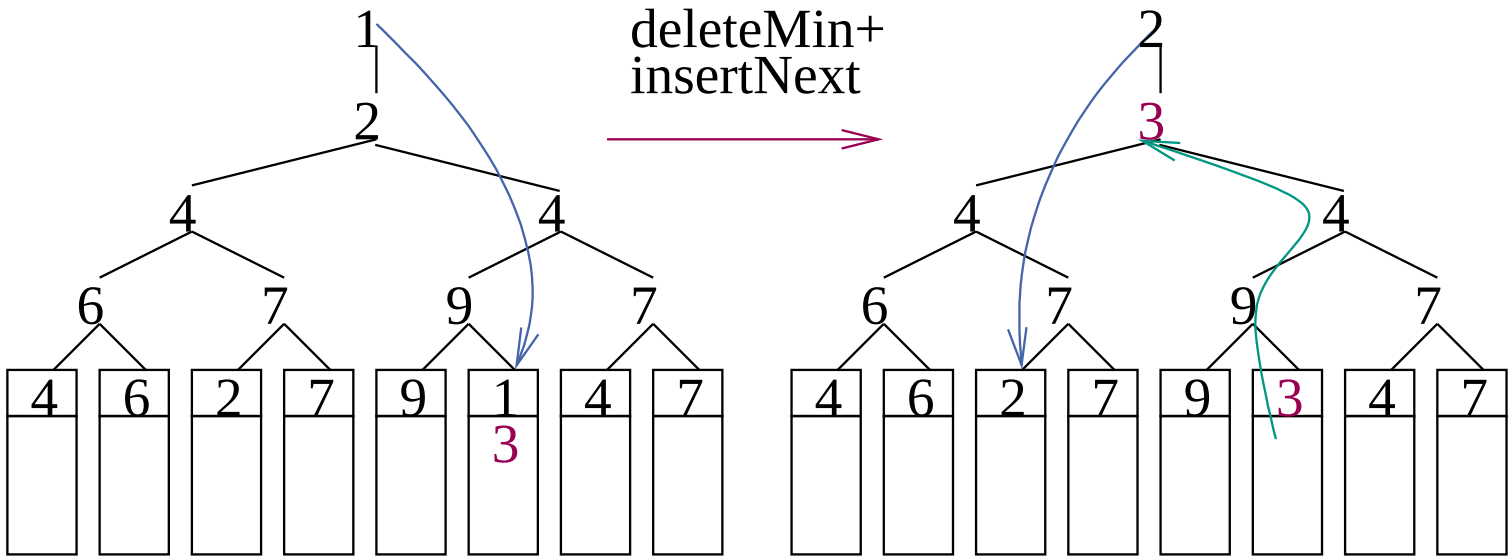
Assume $k = 2^K$ runs

K level complete binary tree

Leaves: smallest current element of each run

Internal nodes: loser of a competition for being smallest

Above root: global winner



Why Tournament Trees

- Exactly $\log k$ element comparisons
- Implicit layout in an array $\rightsquigarrow$ simple index arithmetics (shifts)
- Predictable load instructions and index computations

(Unrollable) inner loop:

```
for (int i=(winnerIndex+kReg)>>1; i>0; i>>=1){
  currentPos = entry + i;
  currentKey = currentPos->key;
  if (currentKey < winnerKey) {
    currentIndex      = currentPos->index;
    currentPos->key   = winnerKey;
    currentPos->index = winnerIndex;
    winnerKey         = currentKey;
    winnerIndex       = currentIndex;}}
```

Overlapping I/O and Computation

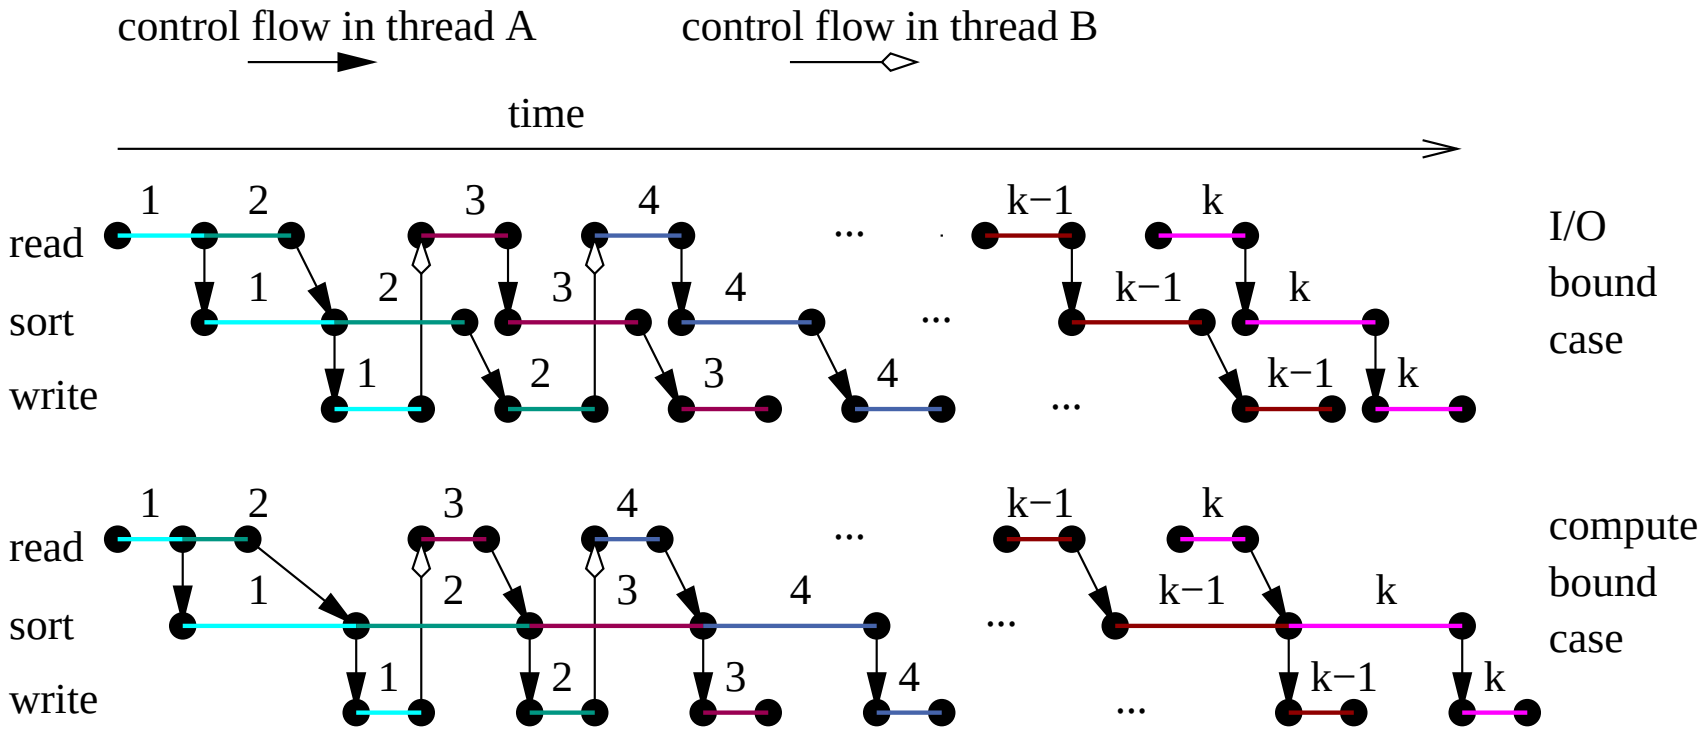
- One thread for each disk (or asynchronous I/O)
- Possibly additional threads
- Blocks filled with elements are passed by references between different buffers

Overlapping During Run Formation

First post read requests for runs 1 and 2

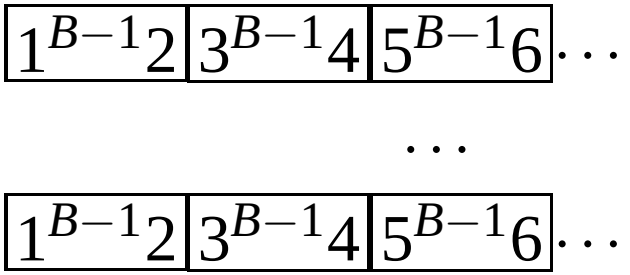
Thread A: Loop { wait-read i; sort i; post-write i};

Thread B: Loop { wait-write i; post-read $i+2$};

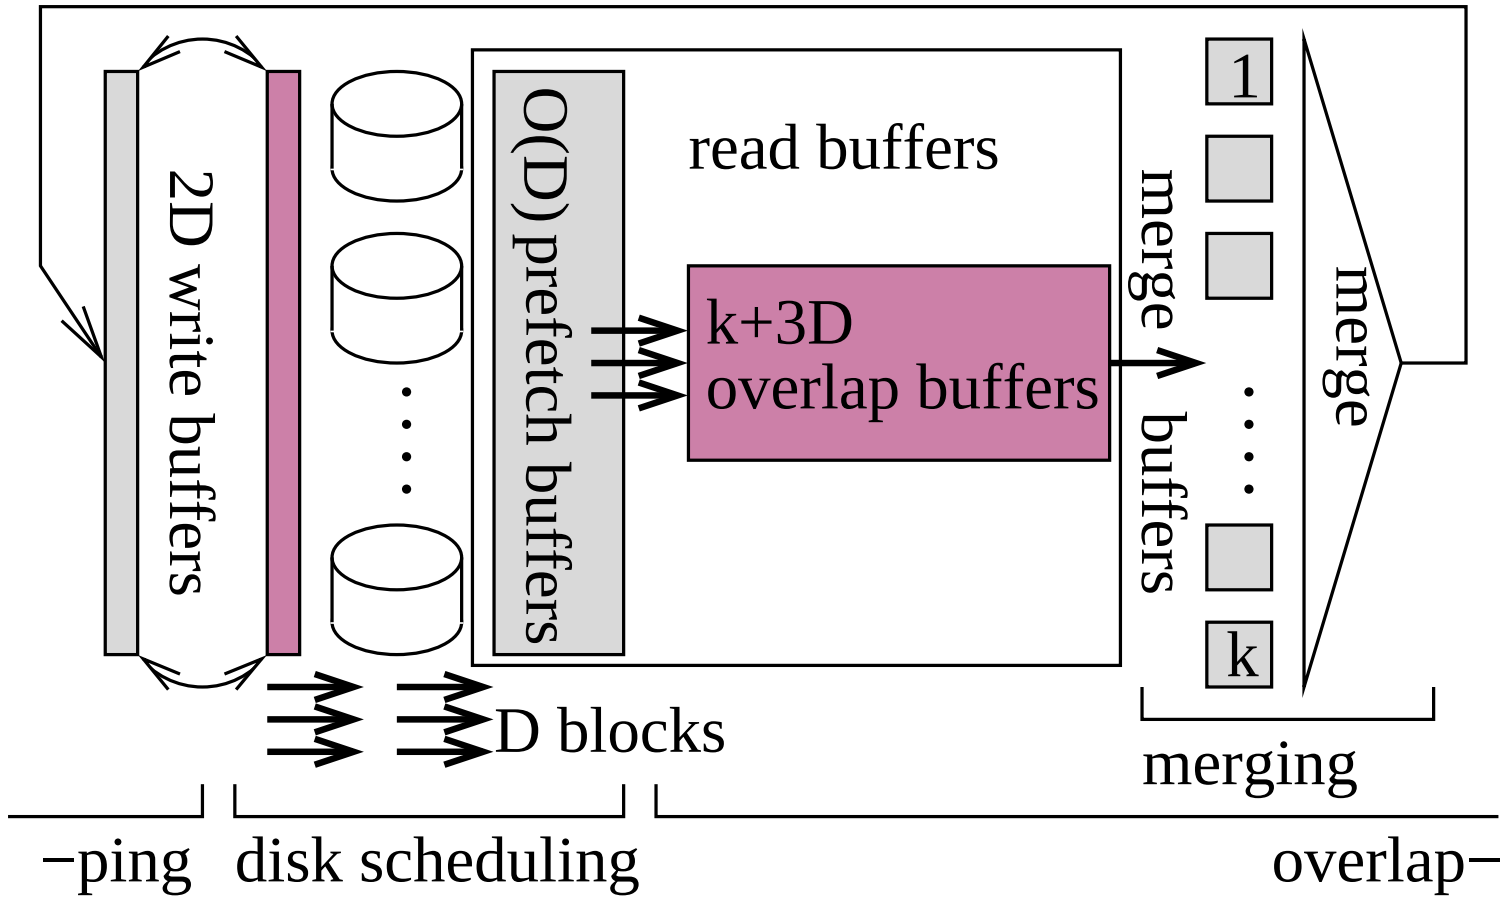


Overlapping During Merging

Bad example:



Overlapping During Merging



I/O Threads: Writing has priority over reading

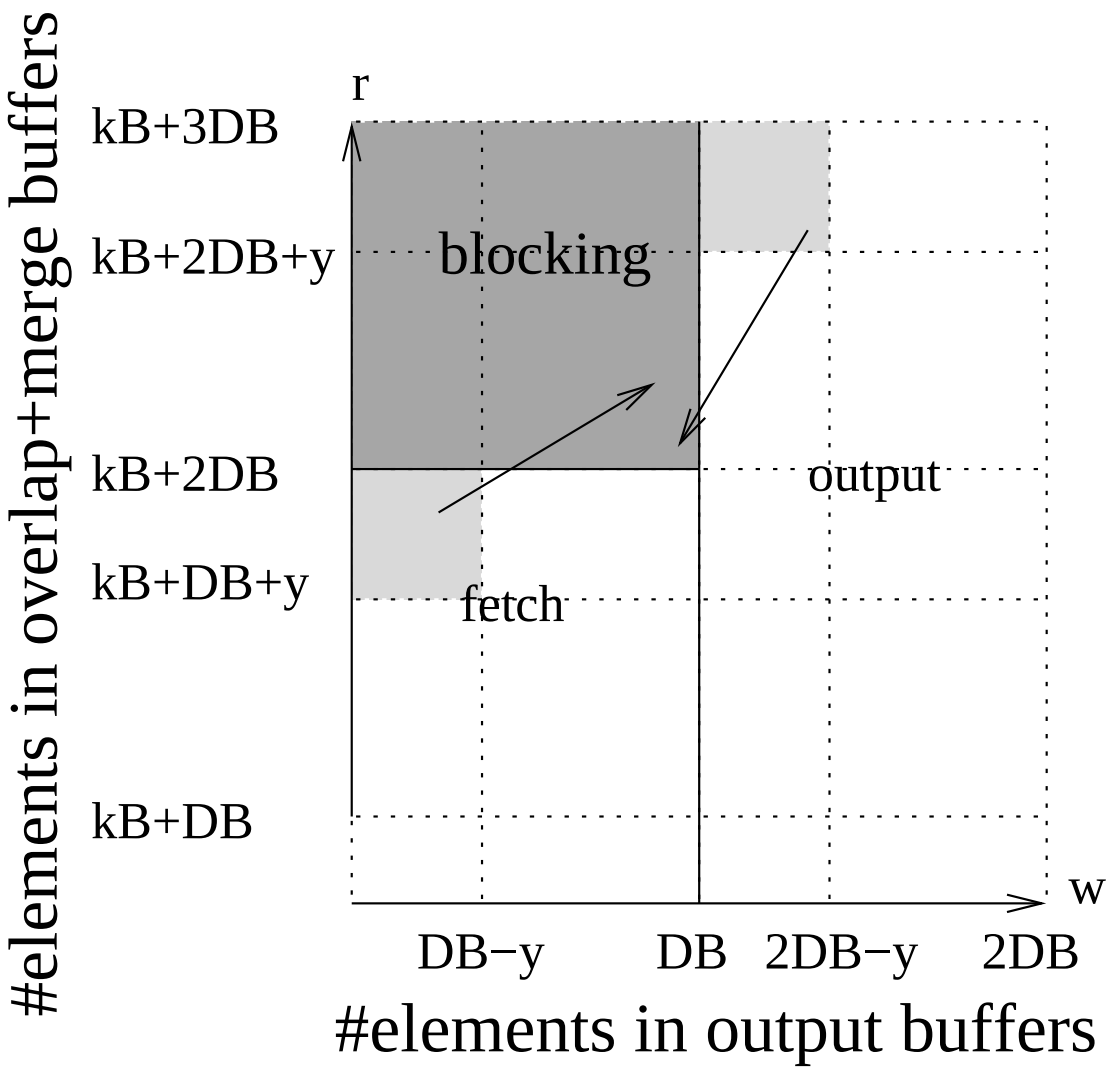
I/O bound case: The I/O thread never blocks

$y =$ # of elements merged during one I/O step.

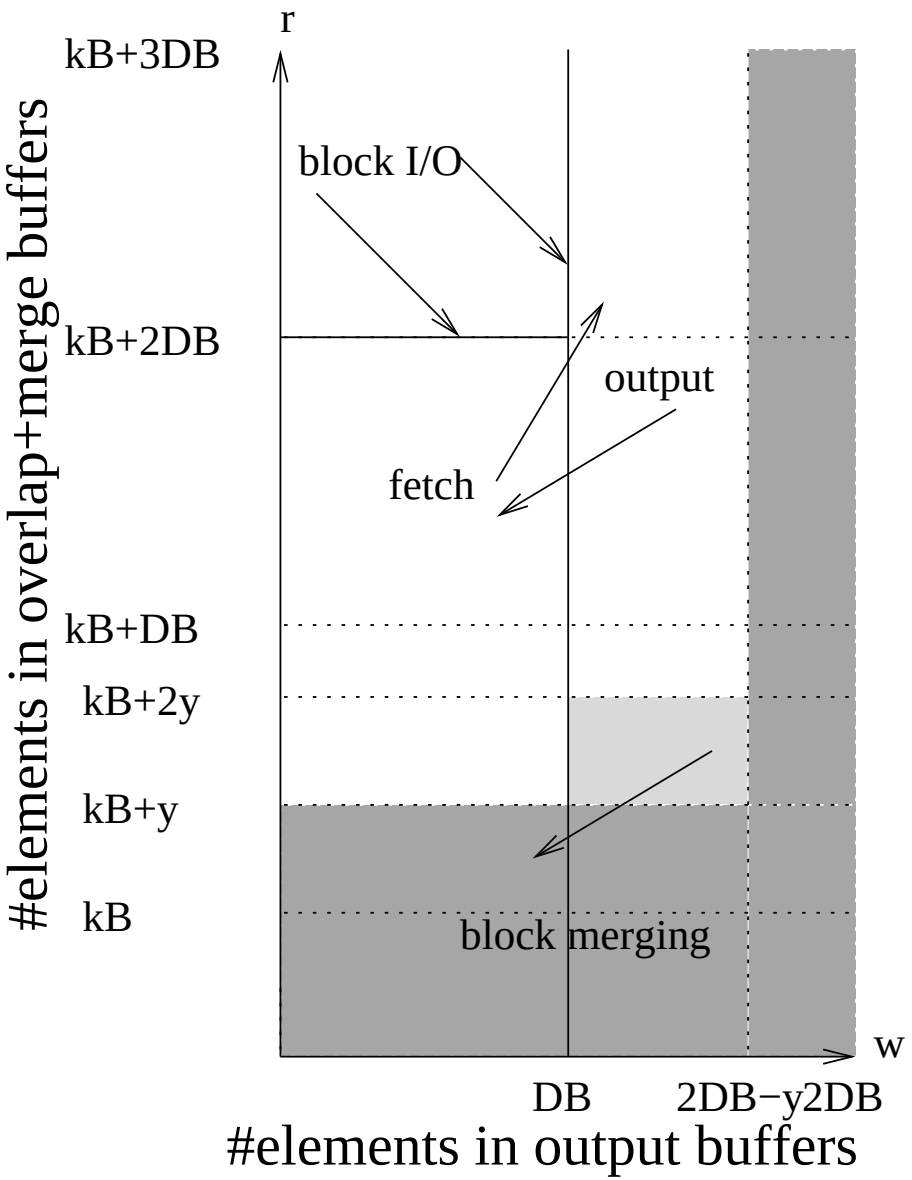
I/O bound $\rightsquigarrow$

$y > \frac{DB}{2}$

$y \leq DB$



Compute bound case: The merging thread never blocks



Hardware (mid 2002)

Linux

(2 × 2GHz Xeon × 2 Threads)

Several 66 MHz PCI-buses

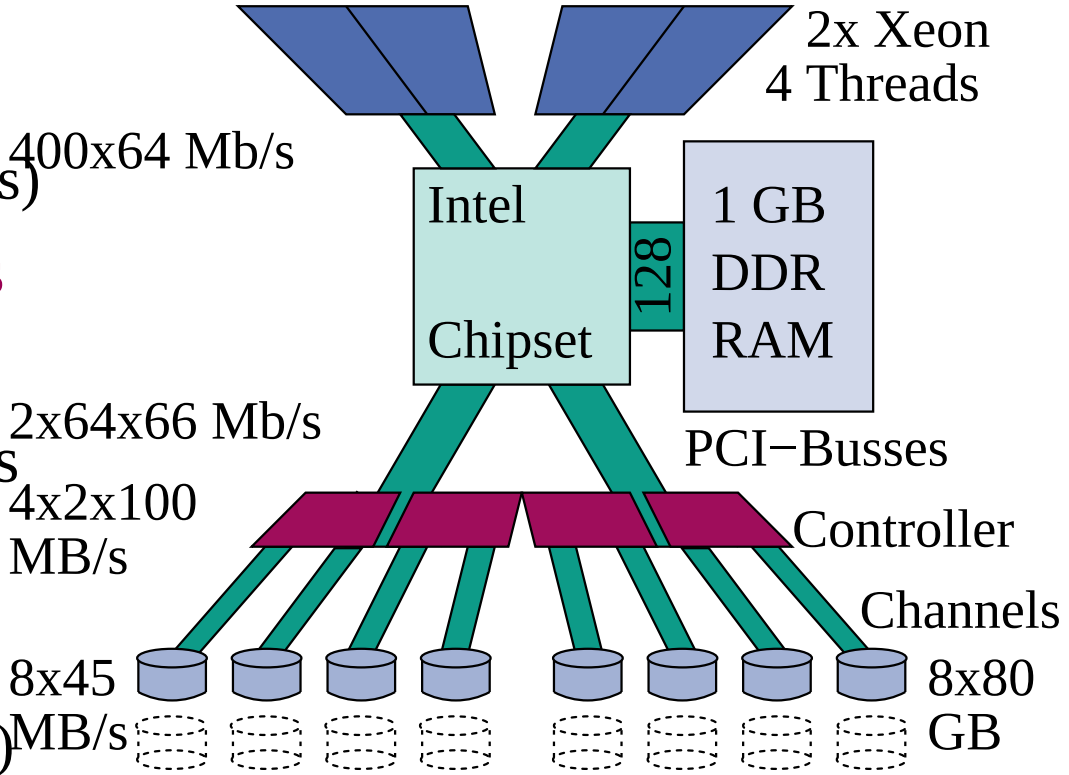
(SuperMicro P4DPE3)

Several fast IDE controllers

(4 × Promise Ultra100 TX2)

Many fast IDE disks

(8× IBM IC35L080AVVA07)



---

cost effective I/O-bandwidth (real 360 MB/s for ≈ 3000)€

Hardware (end 2009) geschätzt

Linux

(2 $\times$ 2.4 GHz Xeon E5530 $\times$ 4 Cores $\times$ 2 Threads)

PCIe x8 SATA controller

16–24 1.5 TByte SATA disks

(8$\times$ IBM IC35L080AVVA07)

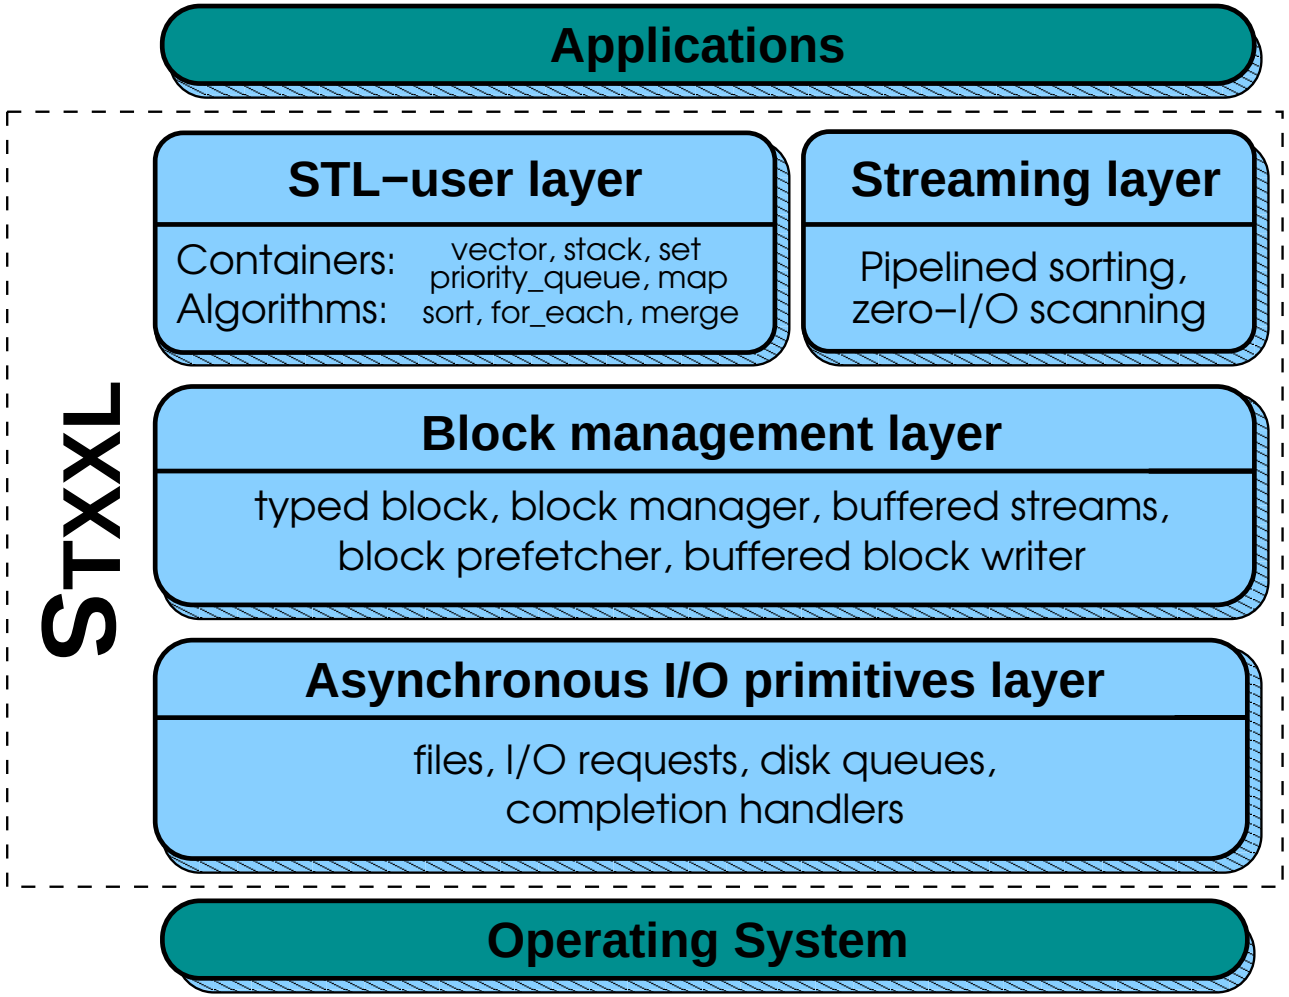
24 GByte RAM

---

cost effective I/O-bandwidth (real 2 GB/s for $\approx$ 6000) €

Software Interface

Goals: efficient + simple + compatible



Default Measurement Parameters

$t :=$ number of available buffer blocks

Input Size: 16 GByte

Element Size: 128 Byte

Keys: Random 32 bit integers

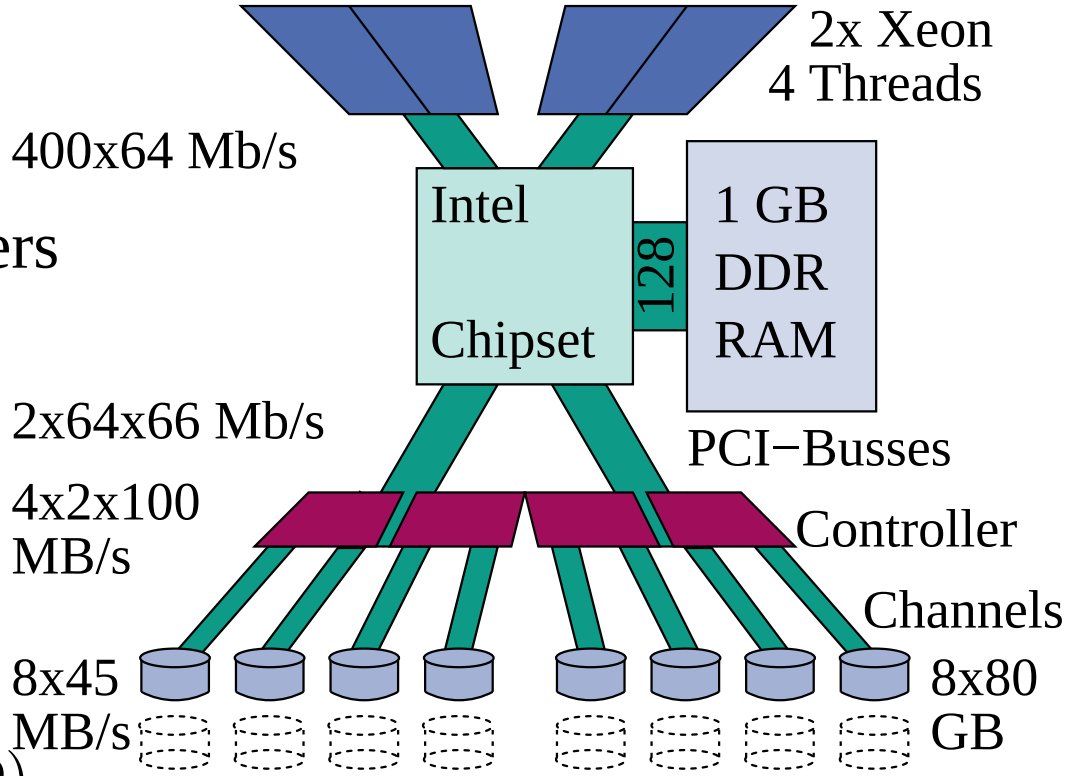
Run Size: 256 MByte

Block size B: 2 MByte

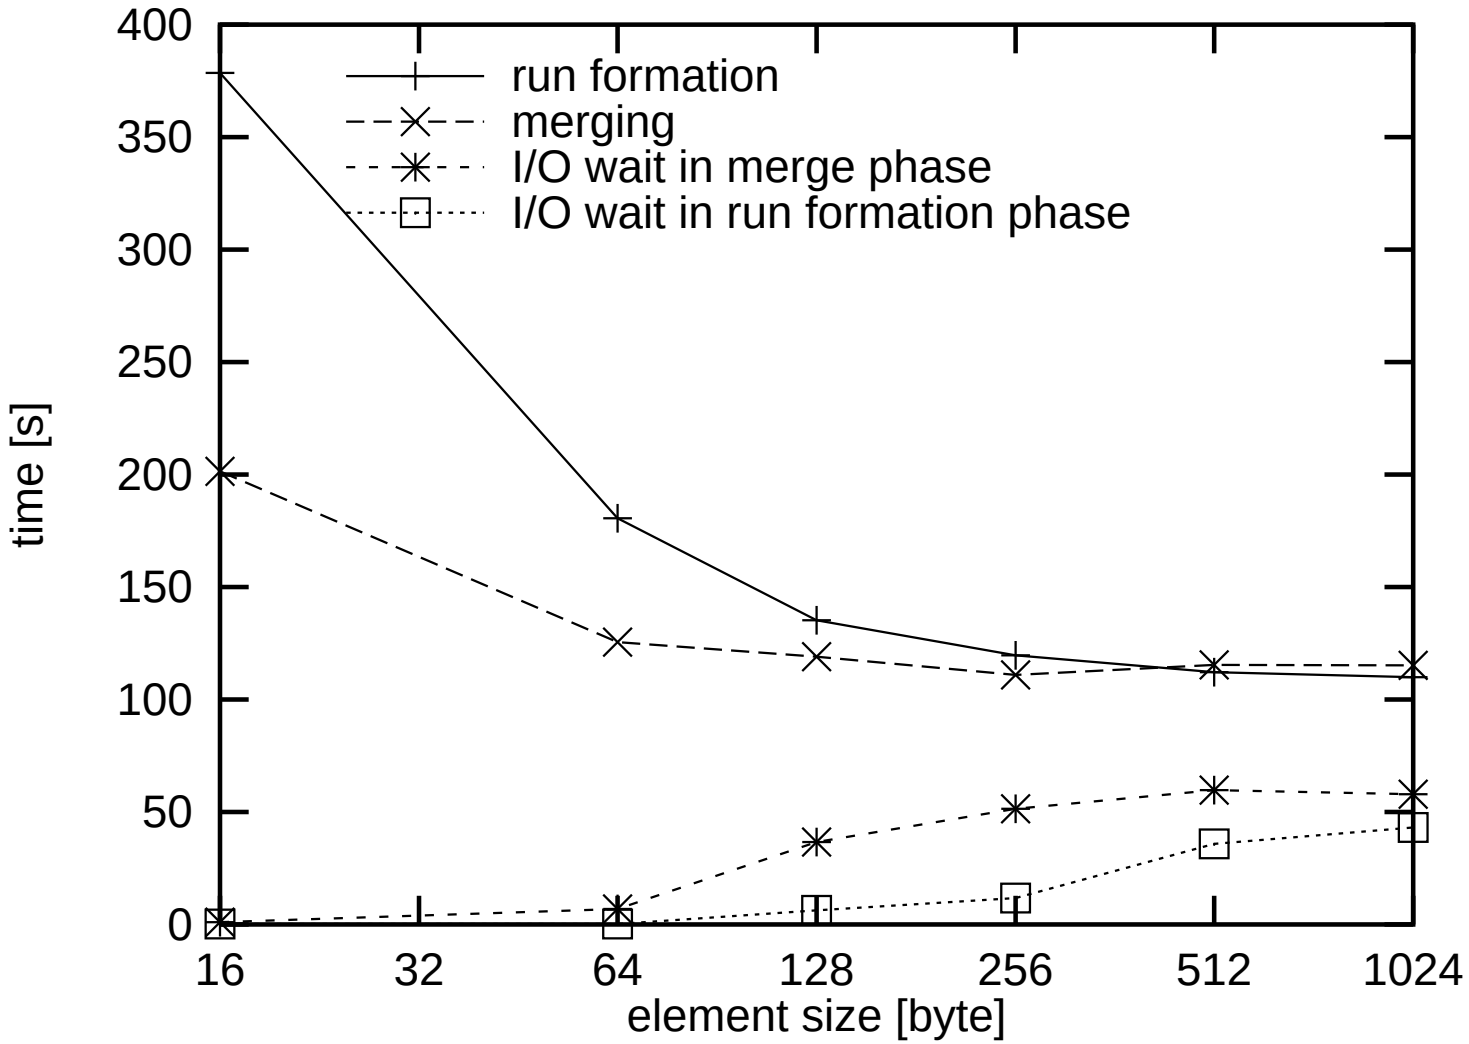
Compiler: g++ 3.2 -O6

Write Buffers: $\max(t/4, 2D)$

Prefetch Buffers: $2D + \frac{3}{10}(t - w - 2D)$



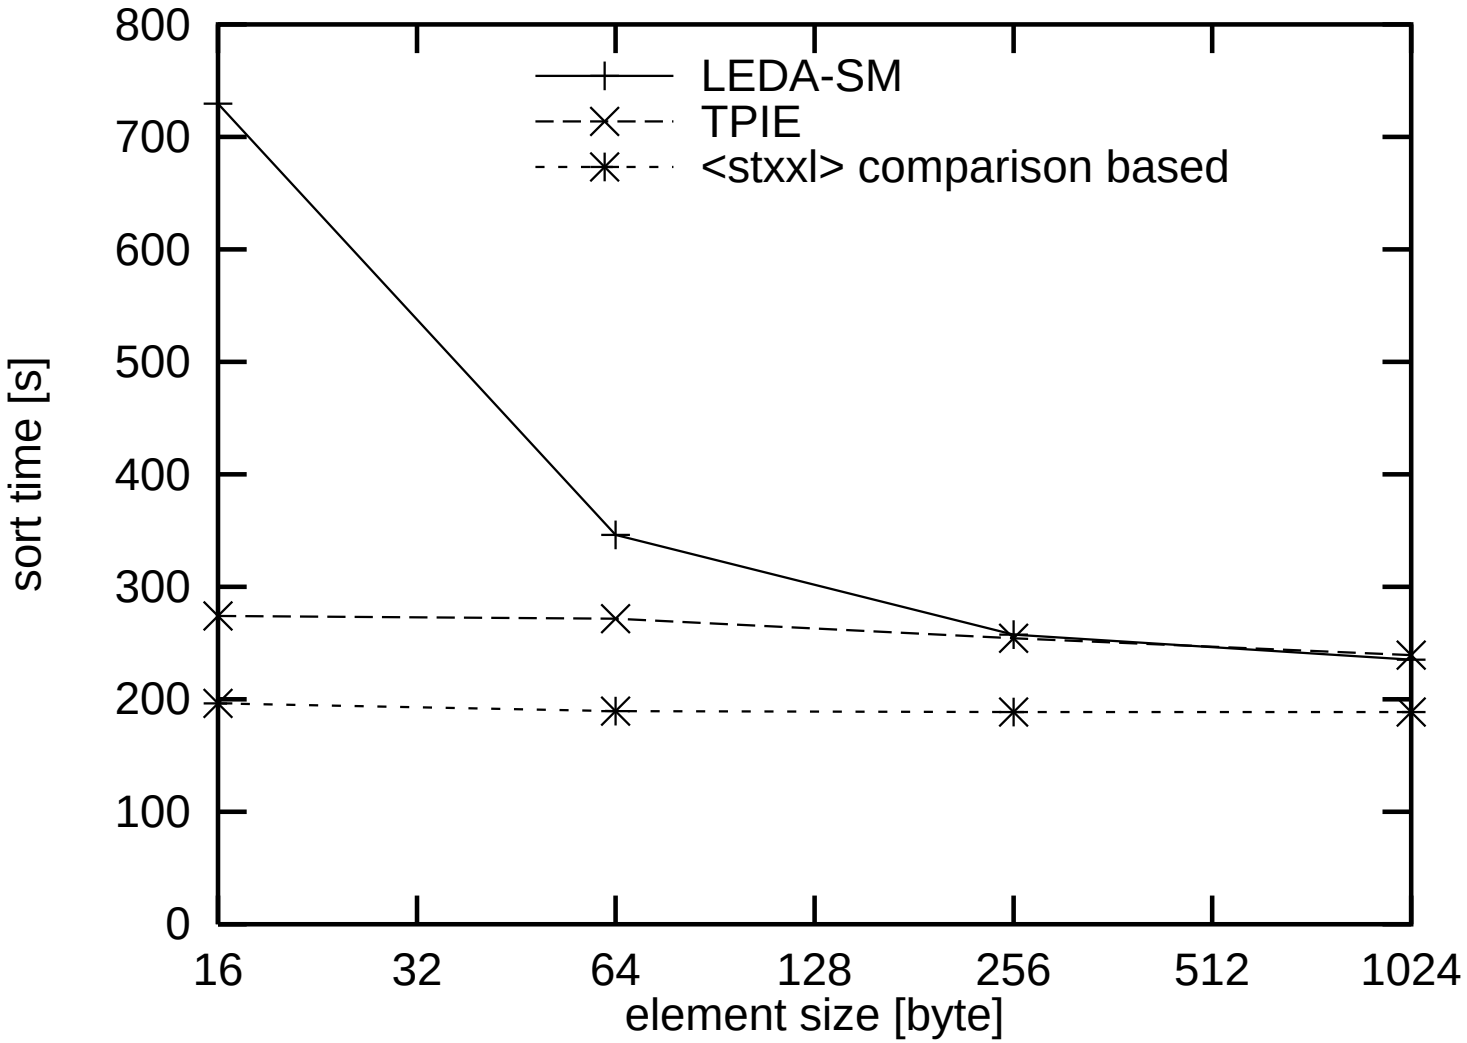
Element sizes (16 GByte, 8 disks)



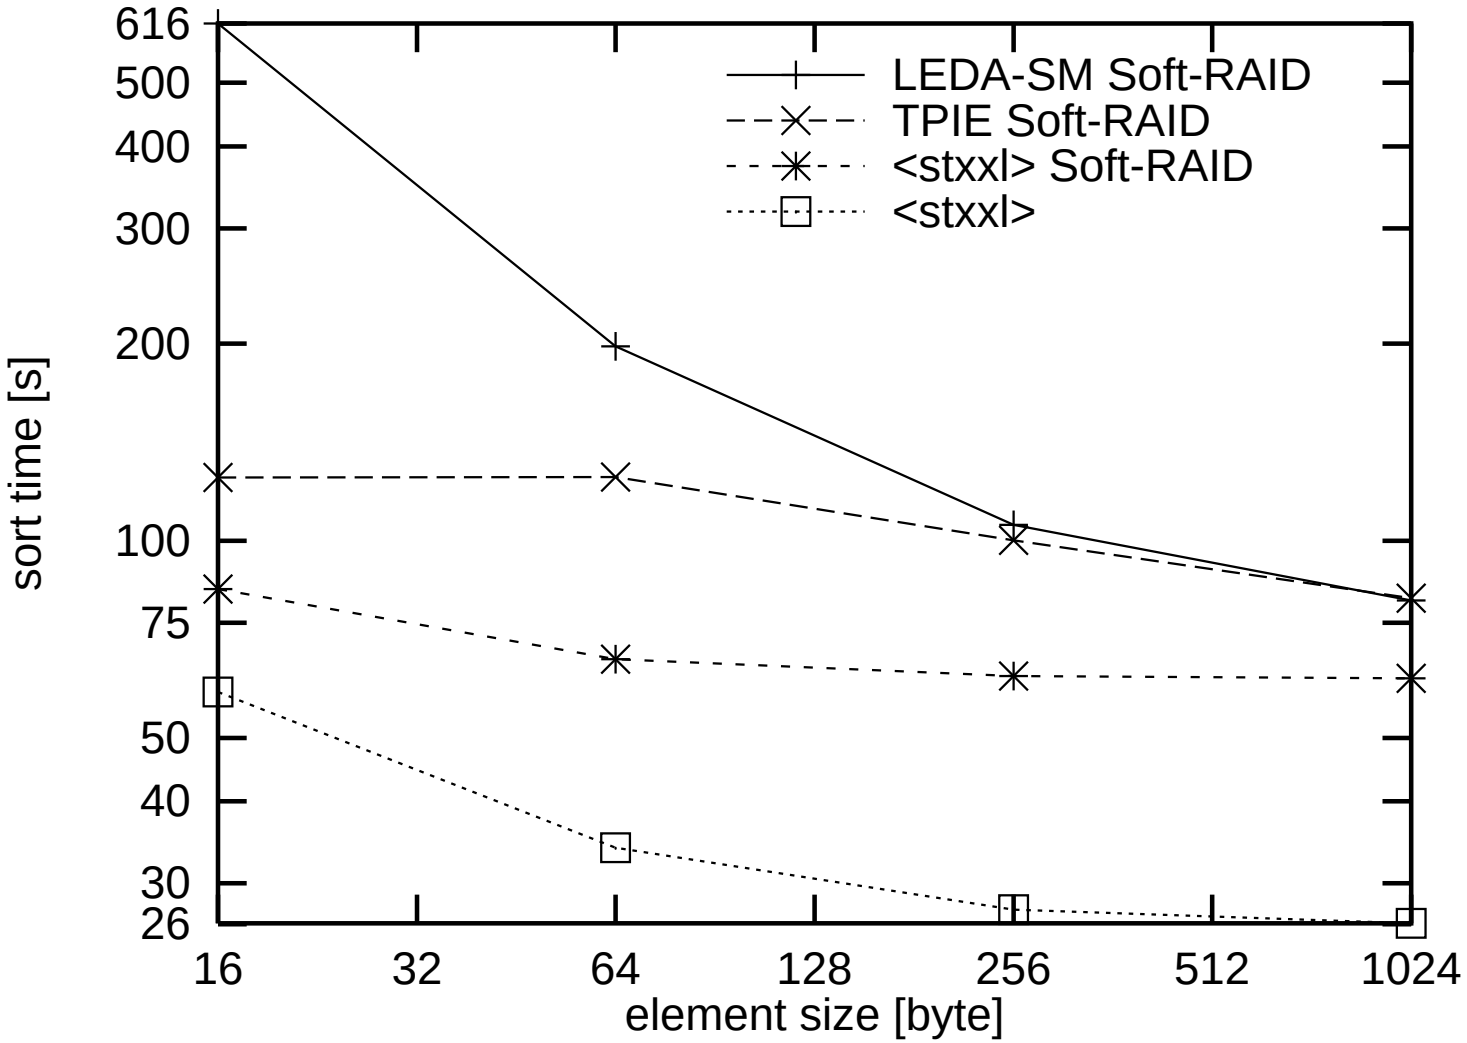
parallel disks $\rightsquigarrow$ bandwidth "for free" $\rightsquigarrow$ internal work, overlapping are relev

Earlier Academic Implementations

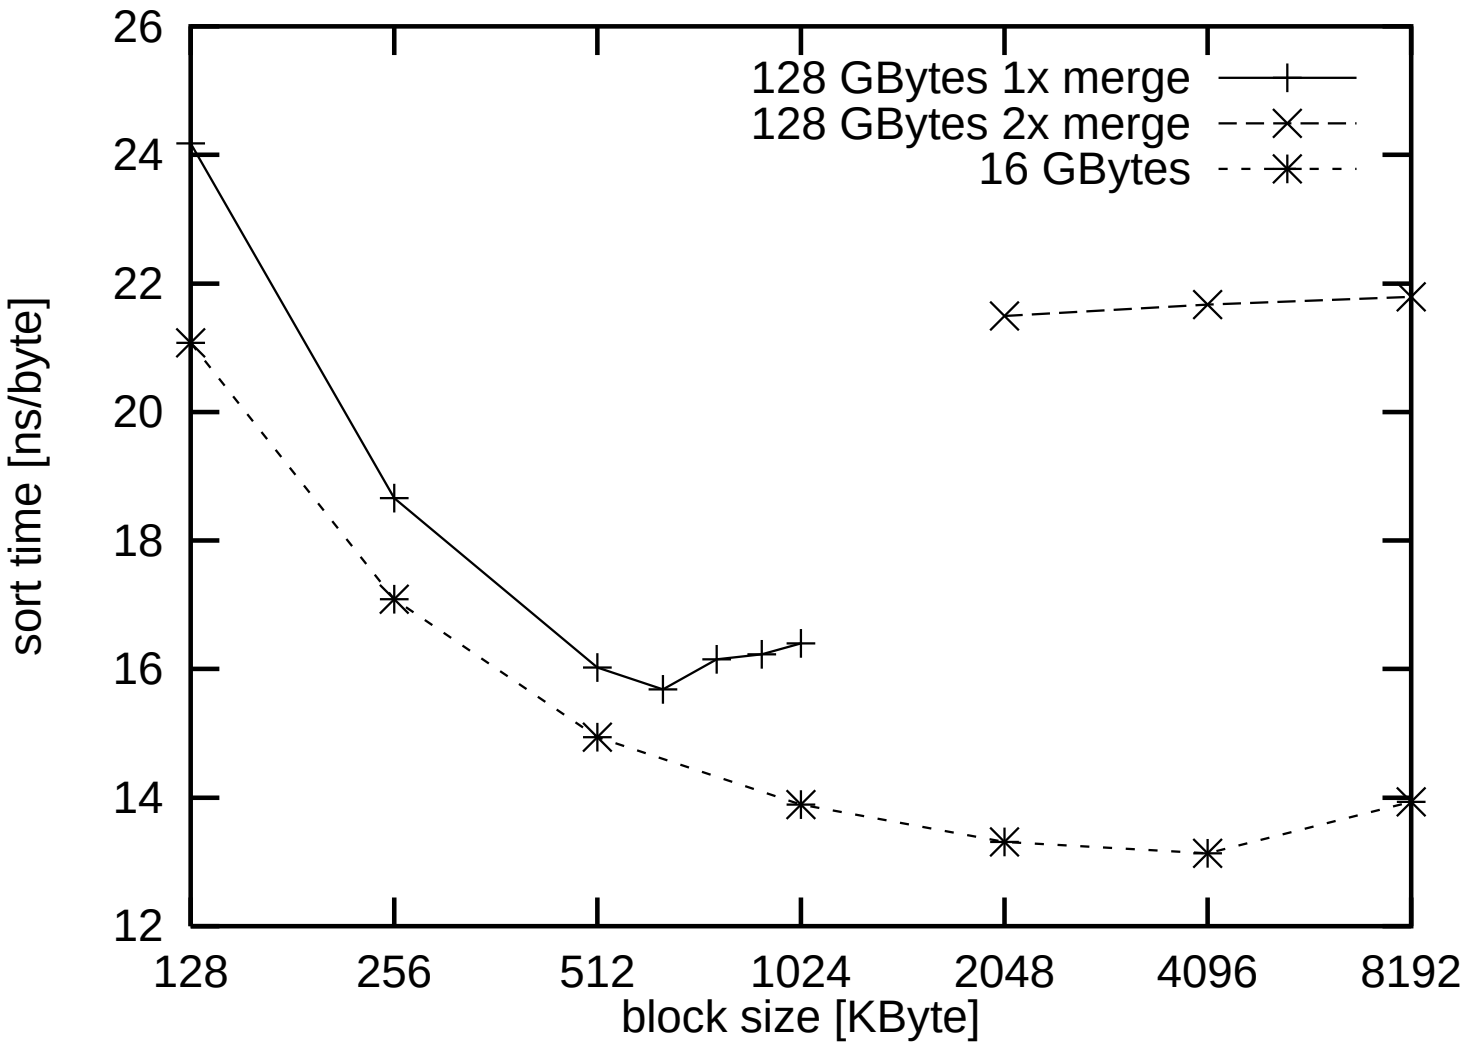
Single Disk, at most 2 GByte, old measurements use artificial M



Earlier Acad. Implementations: Multiple Disks



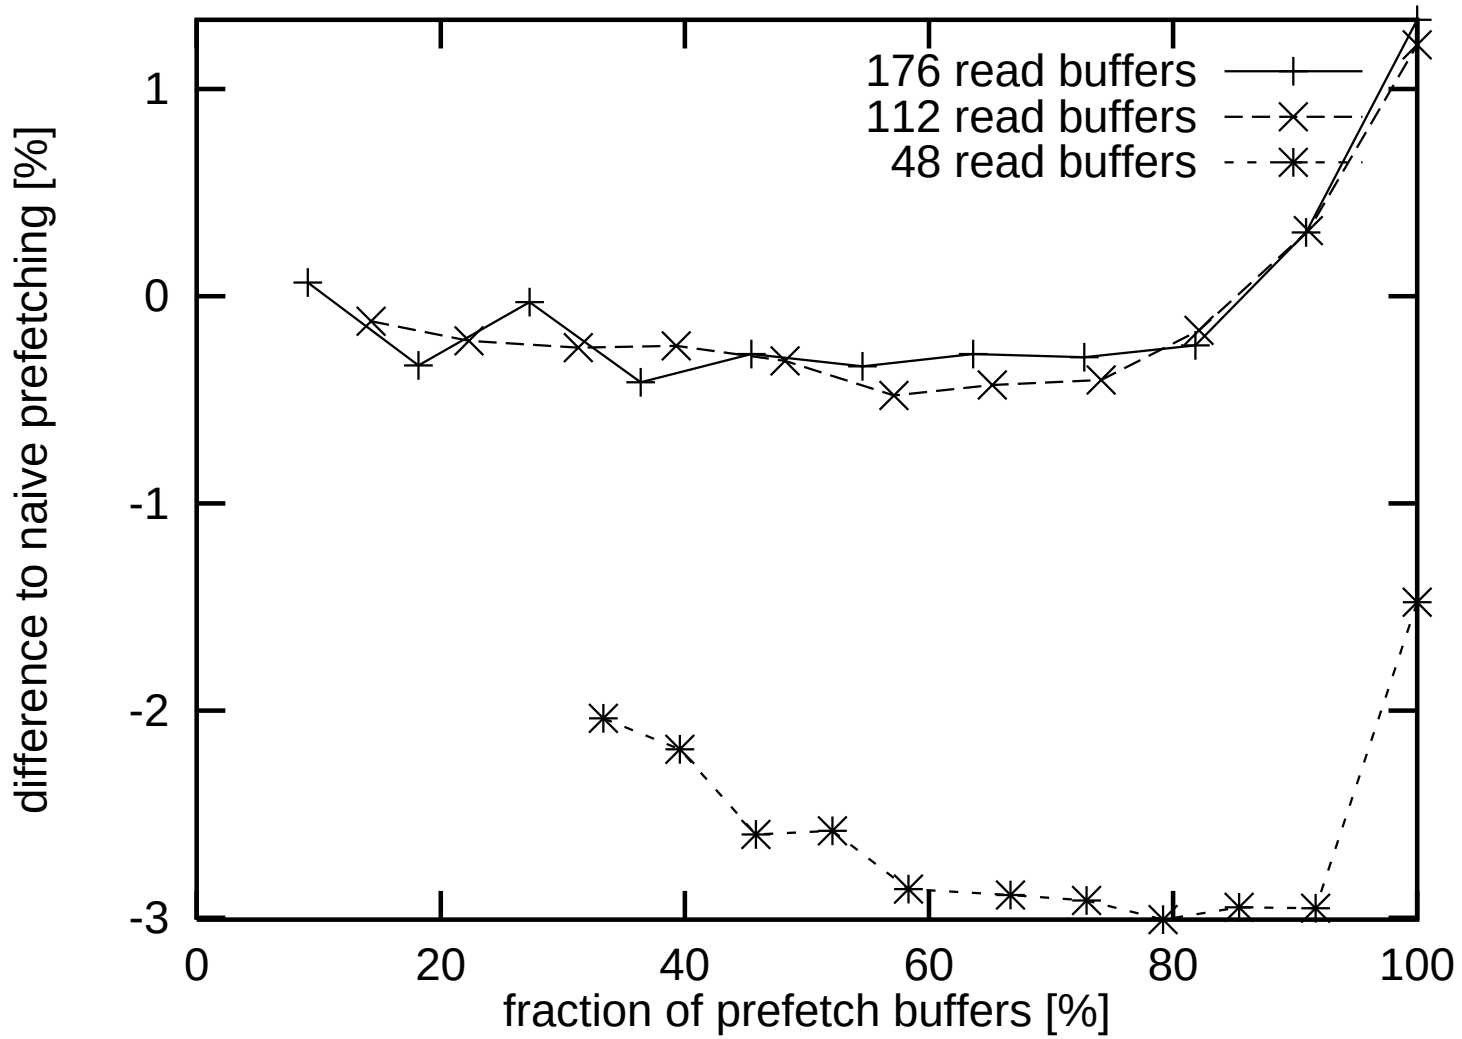
What are good block sizes (8 disks)?



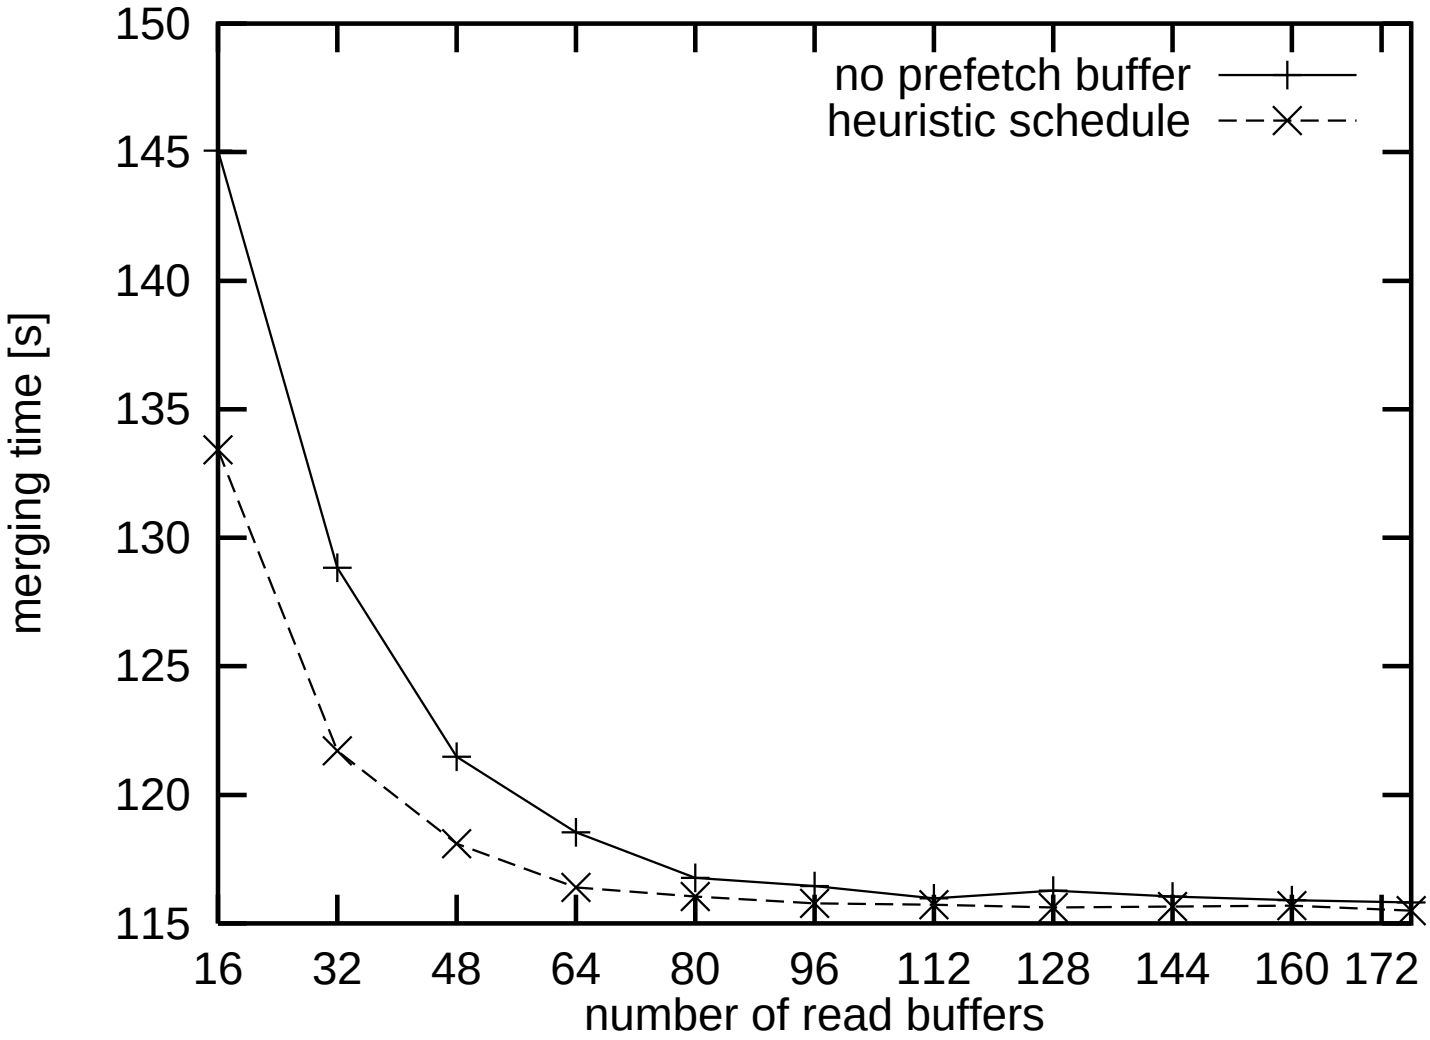
B is not a technology constant

Optimal Versus Naive Prefetching

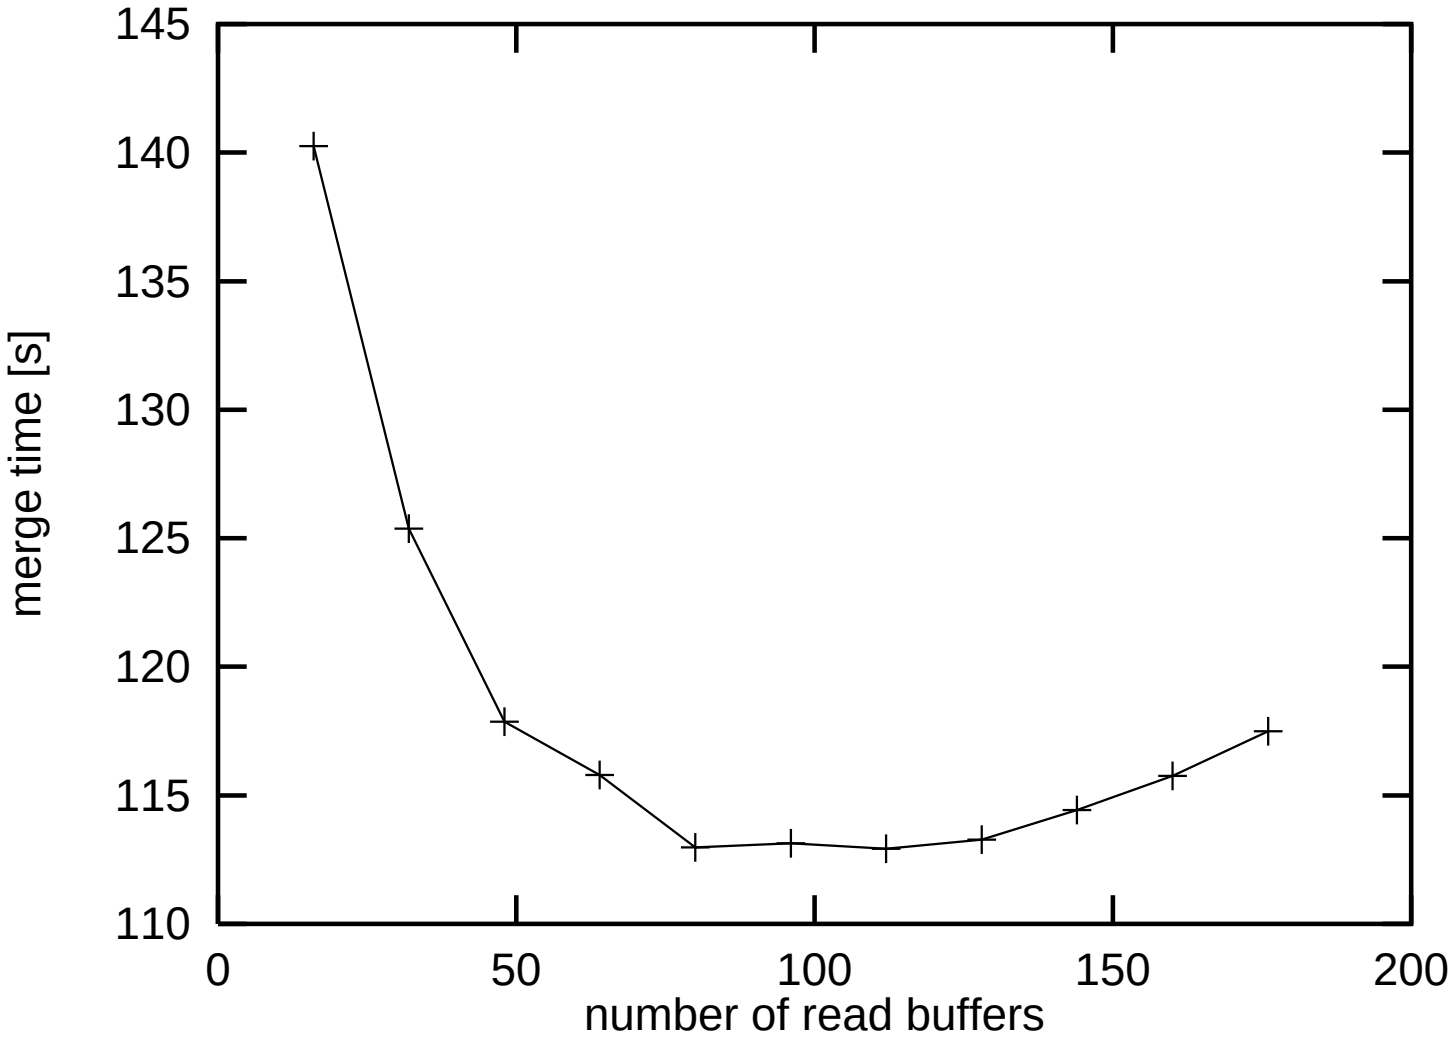
Total merge time



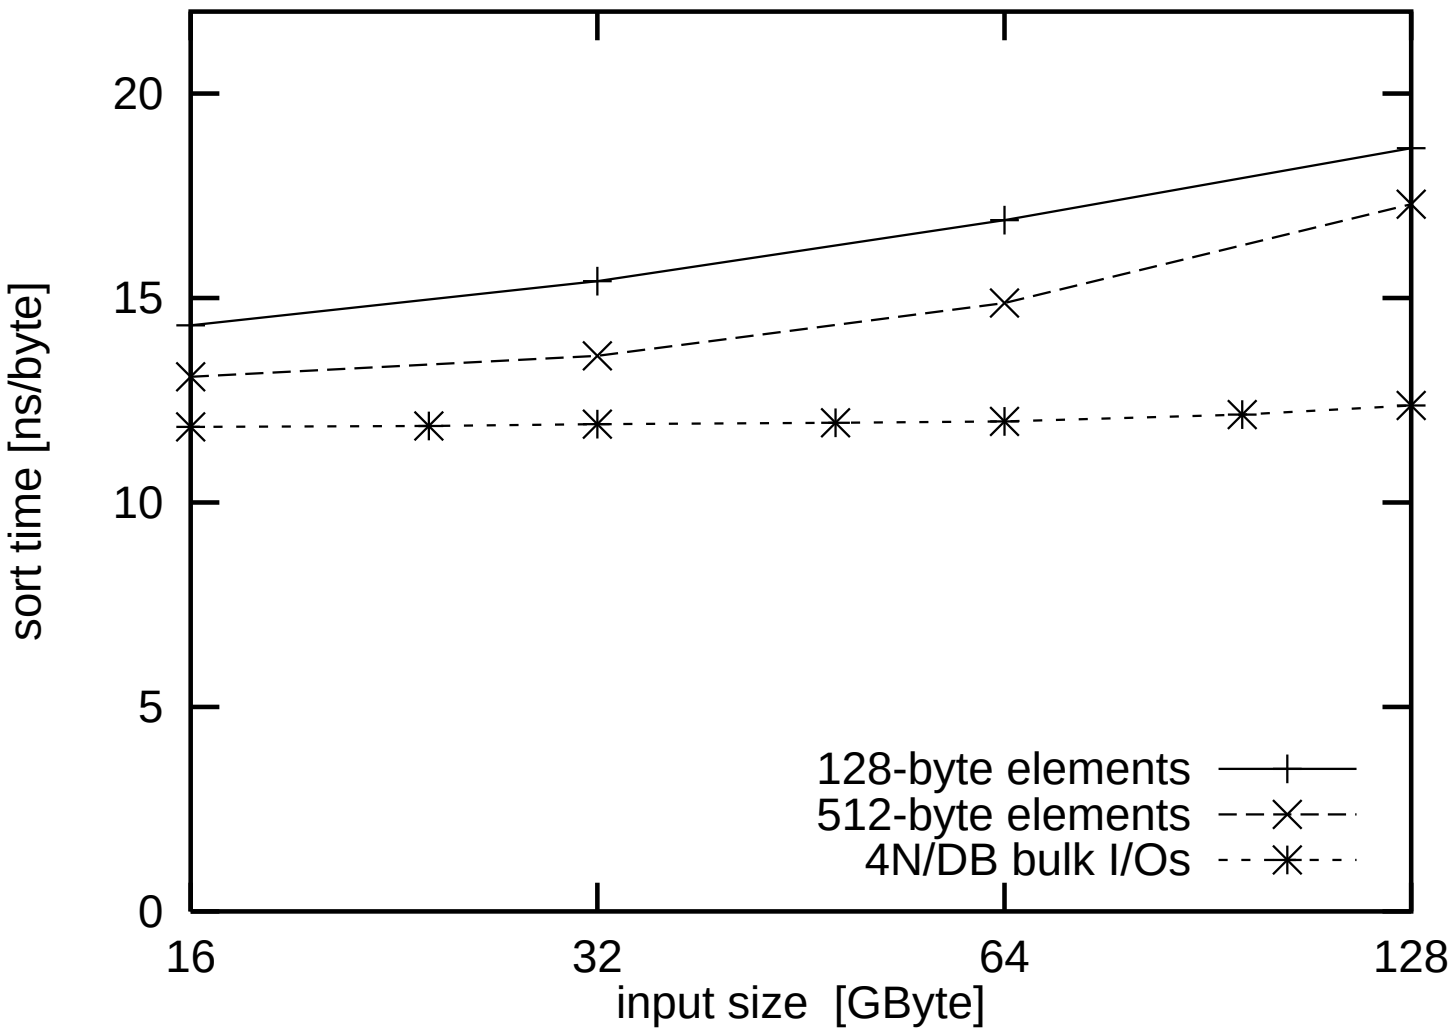
Impact of Prefetch and Overlap Buffers



Tradeoff: Write Buffer Size Versus Read Buffer Size



Scalability



Discussion

- Theory and practice harmonize
- No expensive server hardware necessary (SCSI,...)
- No need to work with artificial M
- No 2/4 GByte limits
- Faster than academic implementations
- (Must be) as fast as commercial implementations but with performance guarantees
- Blocks are much larger than often assumed. Not a technology constant
- Parallel disks $\rightsquigarrow$
  bandwidth "for free" $\rightsquigarrow$ don't neglect internal costs

More Parallel Disk Sorting?

Pipelining: Input does not come from disk but from a logical input stream. Output goes to a logical output stream

$\rightsquigarrow$ only half the I/Os for sorting

$\rightsquigarrow$ often no I/Os for scanning todo: better overlapping

Parallelism: This is the only way to go for really many disks

Tuning and Special Cases: ssssort, permutations, balance work between merging and run formation?...

Longer Runs: not done with guaranteed overlapping, fast internal sorting !

Distribution Sorting: Better for seeks etc.?

Inplace Sorting: Could also be faster

Determinism: A practical and theoretically efficient algorithm?

Procedure formLongRuns

q, q' : PriorityQueue

for $i := 1$ **to** M **do** q.insert(readElement)

invariant $|q| + |q'| = M$

loop

while $q \neq \emptyset$

writeElement($e :=$ q.deleteMin)

if input exhausted **then** break outer loop

if $e' :=$ readElement $< e$ **then** q'.insert(e')

else q.insert(e')

$q := q'$; $q' := \emptyset$

output q in sorted order; output q' in sorted order

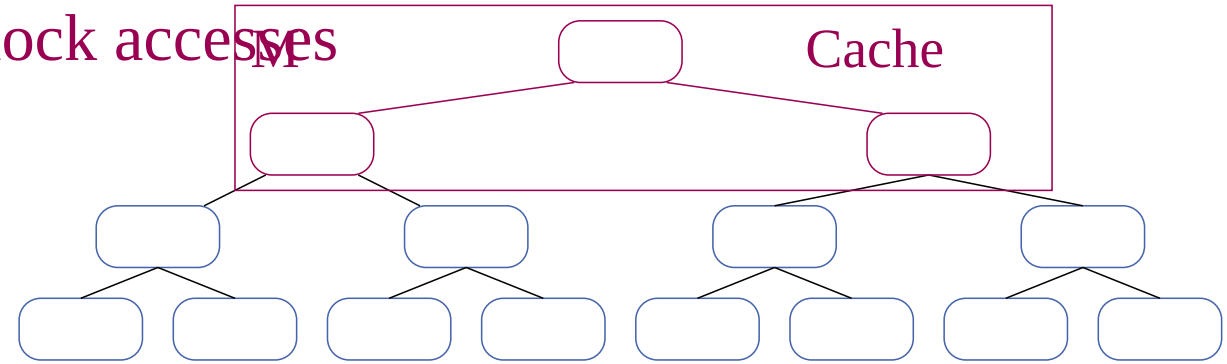
Knuth: average run length $2M$

todo: cache-effiziente Implementierung

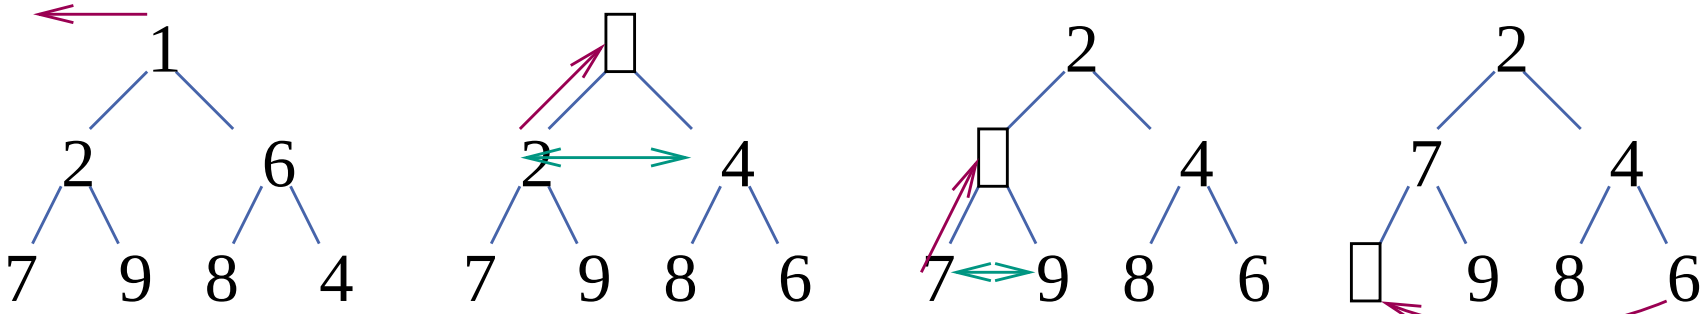
2 Priority Queues (insert, deleteMin)

Binary Heaps best comparison based "flat memory" algorithm

+ On average constant time for insertion
+ On average $\log n + \mathcal{O}(1)$ key comparisons per delete-Min using the "bottom-up" heuristics [Wegener 93].
– $\approx 2\log(n/M)$ block accesses per delete-Min



Bottom Up Heuristics



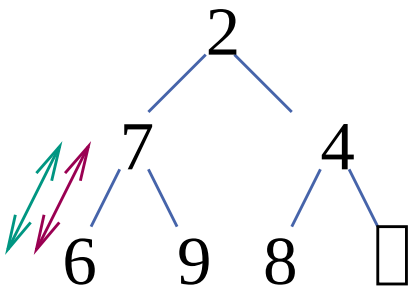
delete Min

O(1)

sift down hole

log(n)

compare swap move



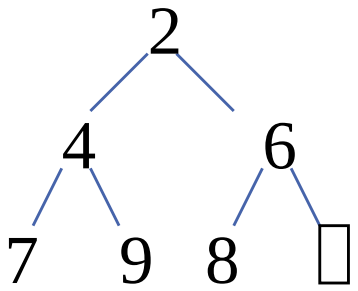
Factor two faster

than naive implementation

sift up

O(1)

average



Der Wettbewerber fit gemacht:

```
int i=1, m=2, t = a[1];
m += (m != n  &&  a[m] > a[m + 1]);
if (t > a[m]) {
  do { a[i] = a[m];
       i    = m;
       m    = 2*i;
       if (m > n) break;
       m += (m != n  &&  a[m] > a[m + 1]);
  } while (t > a[m]);
  a[i] = t;}
```

Keine signifikanten Leistungsunterschiede auf meiner Maschine (heapsort von random integers)

Vergleich

Speicherzugriffe: $\mathcal{O}(1)$ weniger als top down $\mathcal{O}(\log n)$ worst case. bei effizienter Implementierung

Elementvergleiche: $\approx \log n$ weniger für bottom up (average case) aber die sind leicht vorhersagbar

Aufgabe: siftDown mit worst case $\log n + \mathcal{O}(\log \log n)$ Elementvergleichen

Heapkonstruktion

Procedure buildHeapBackwards

    for $i := \lfloor n/2 \rfloor$ **downto** 1 **do** siftDown(i)

Procedure buildHeapRecursive$(i : \mathbb{N})$

    if $4i \leq n$ **then**

        buildHeapRecursive$(2i)$

        buildHeapRecursive$(2i+1)$

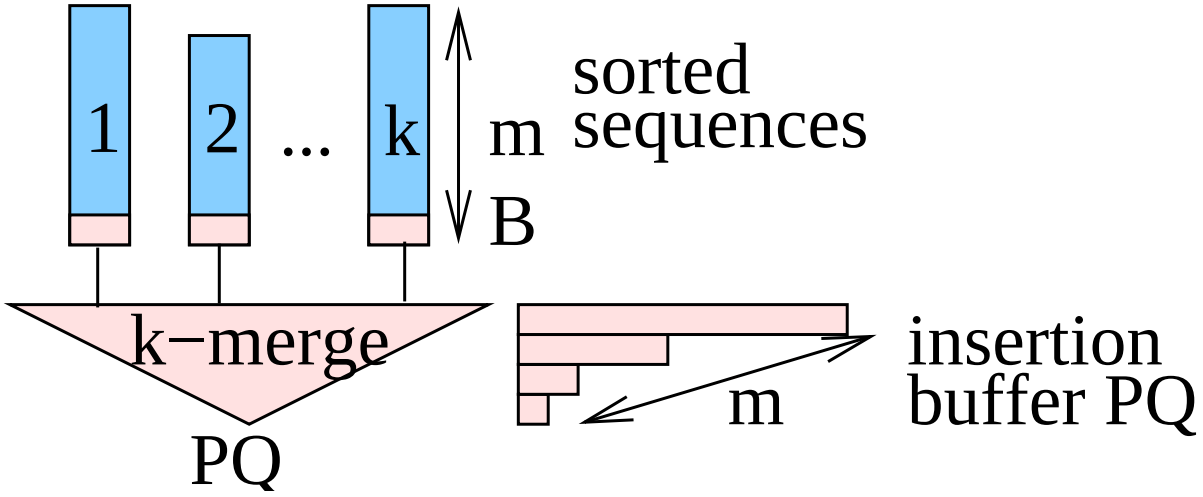
    siftDown(i)

Rekursive Funktion für große Eingaben $2\times$ schneller!

(Rekursion abrollen für 2 unterste Ebenen)

Aufgabe: Erklärung

Mittelgroße PQs – $km \ll M^2/B$ Einfügungen



Insert: Anfangs in insertion buffer.

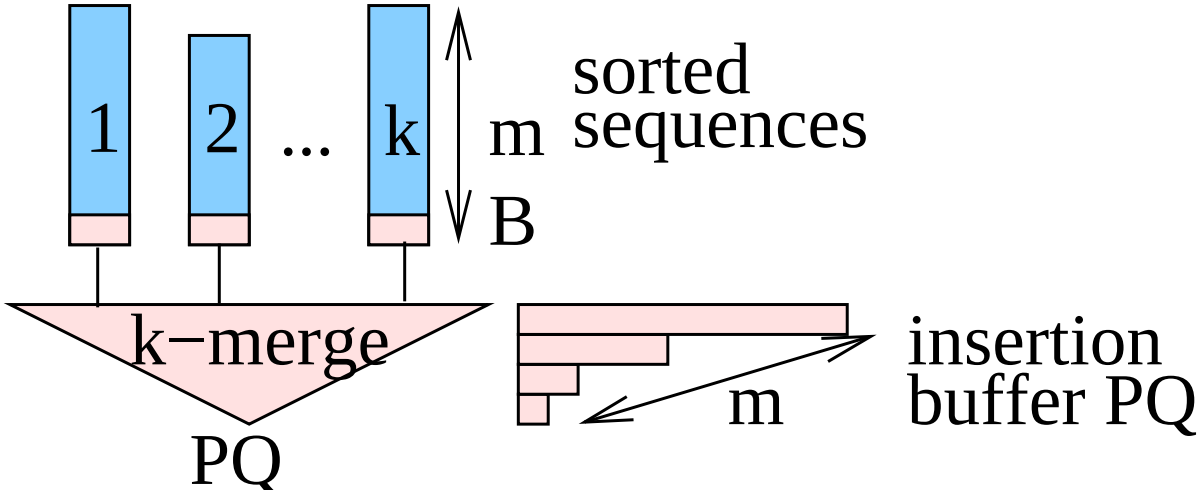
Überlauf $\longrightarrow$

sort; flush; kleinster Schlüssel in merge-PQ

Delete-Min: deleteMin aus der PQ mit kleinerem min

Analyse – I/Os

deleteMin: jedes Element wird $\leq 1\times$ gelesen, zusammen mit B anderen – amortisiert $1/B$ penalty für insert.



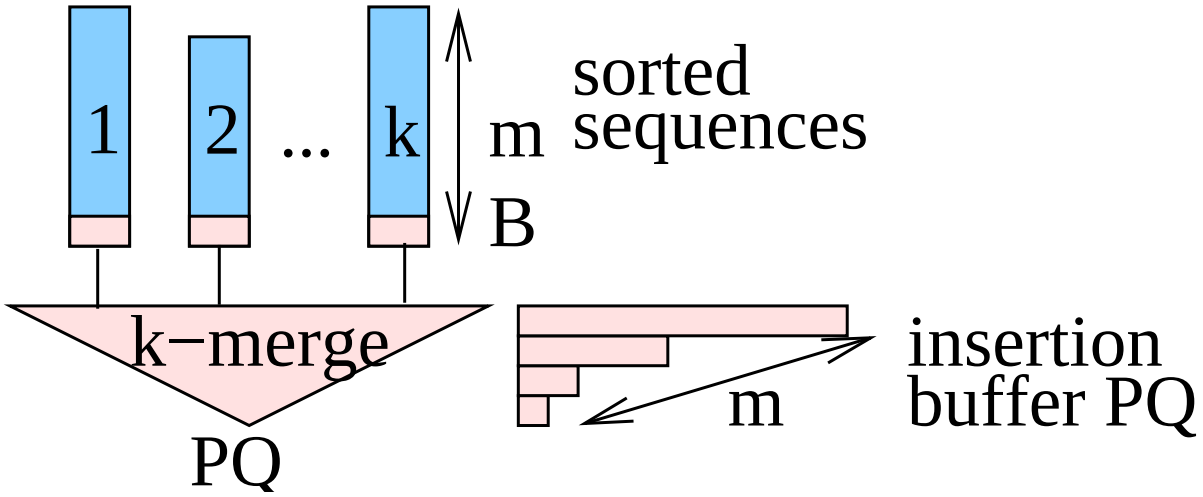
Analyse – Vergleiche (Maß für interne Arbeit)

deleteMin: $1 + \mathcal{O}(\max(\log k, \log m)) = \mathcal{O}(\log m)$

genauere Argumentation: amortisiert $1 + \log k$ bei geeigneter PQ

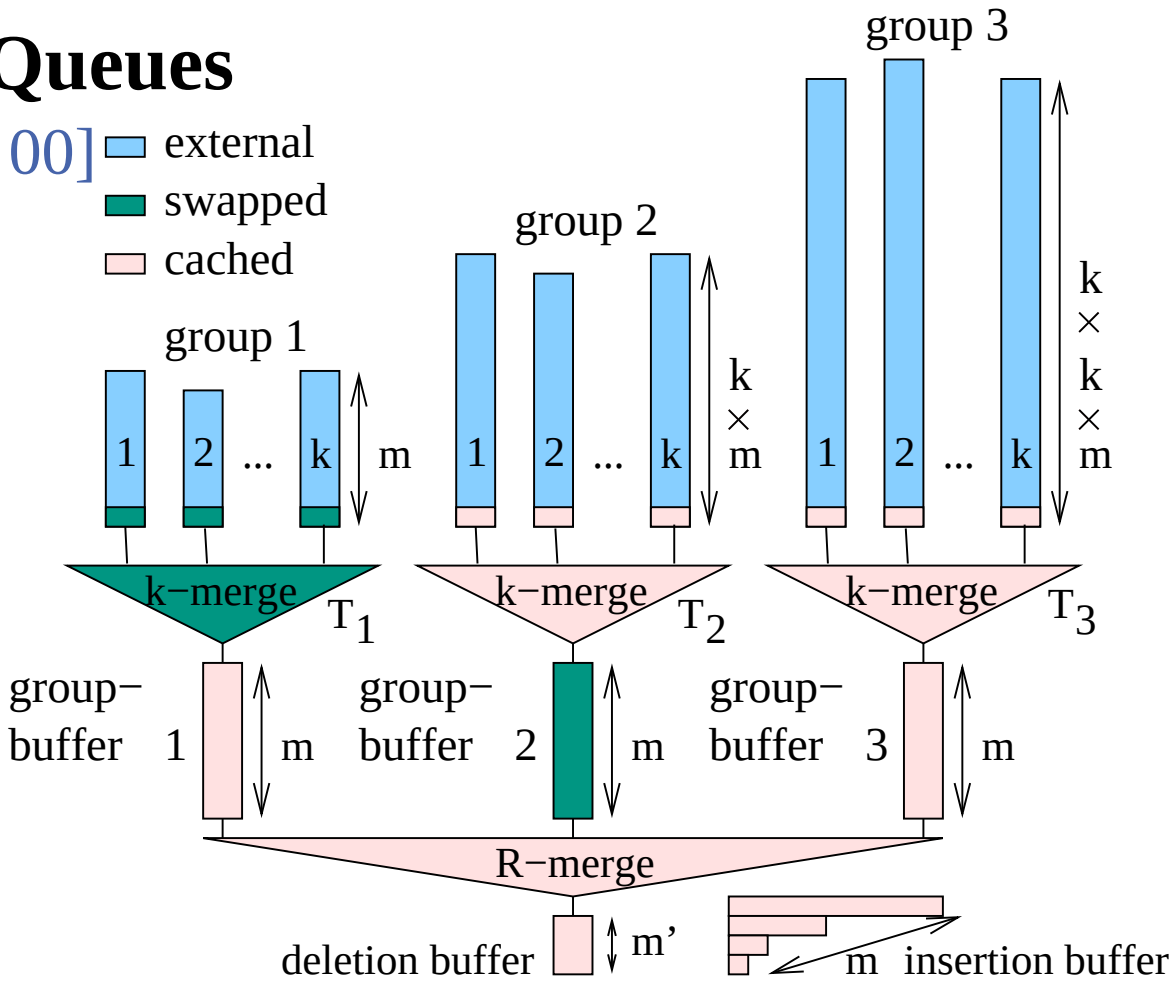
insert: $\approx m \log m$ alle m Ops. Amortisiert $\log m$

Insgesamt nur $\log km$ amortisiert !



Large Queues

[Sanders 00]



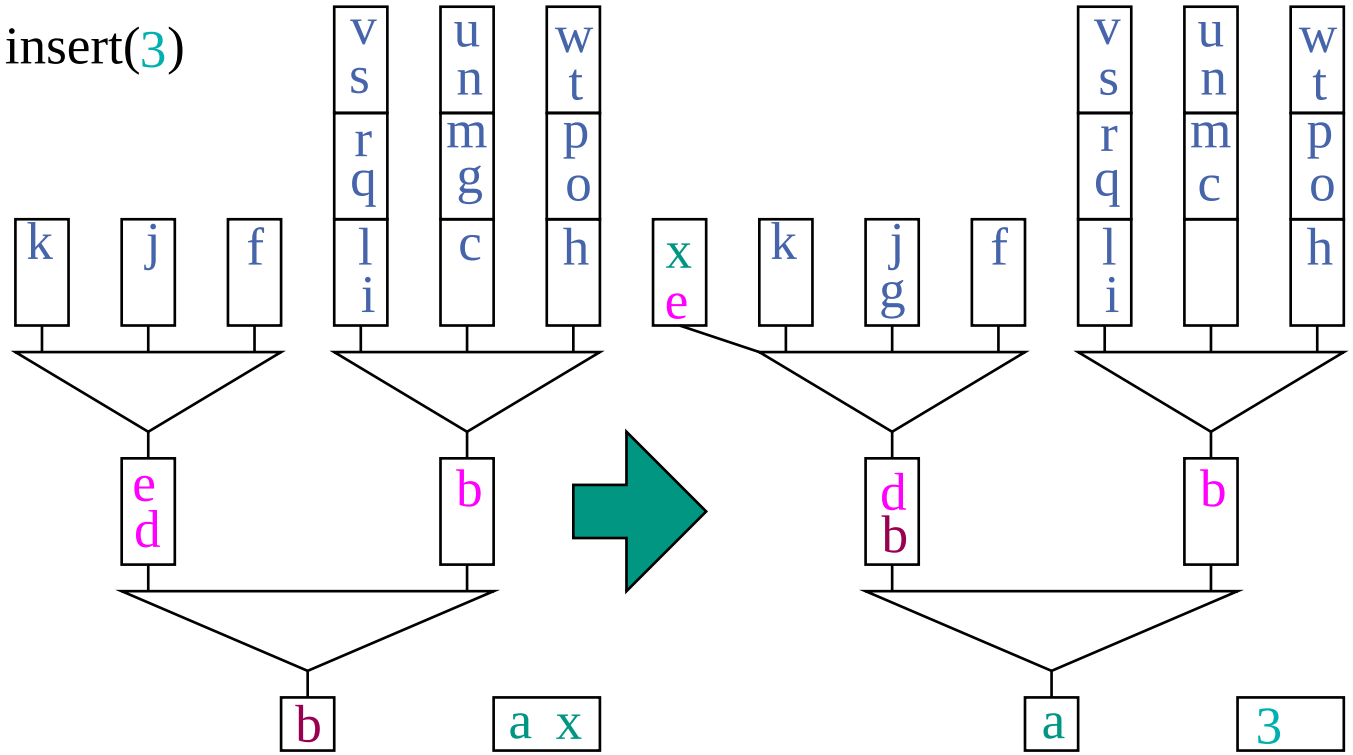
insert: group full $\longrightarrow$ merge group; shift into next group.

merge invalid group buffers and move them into group 1.

Delete-Min: Refill. $m' \ll m$. nothing else

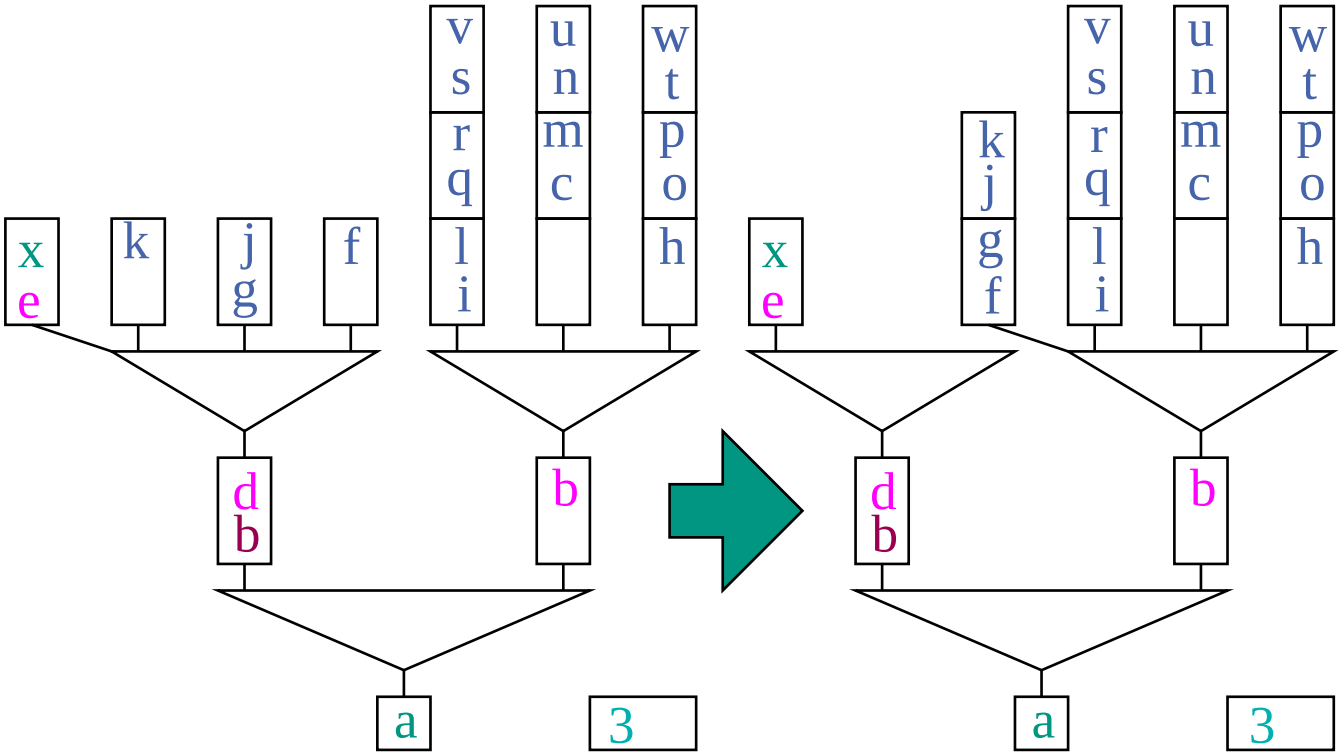
Example

Merge insertion buffer, deletion buffer, and leftmost group buffer



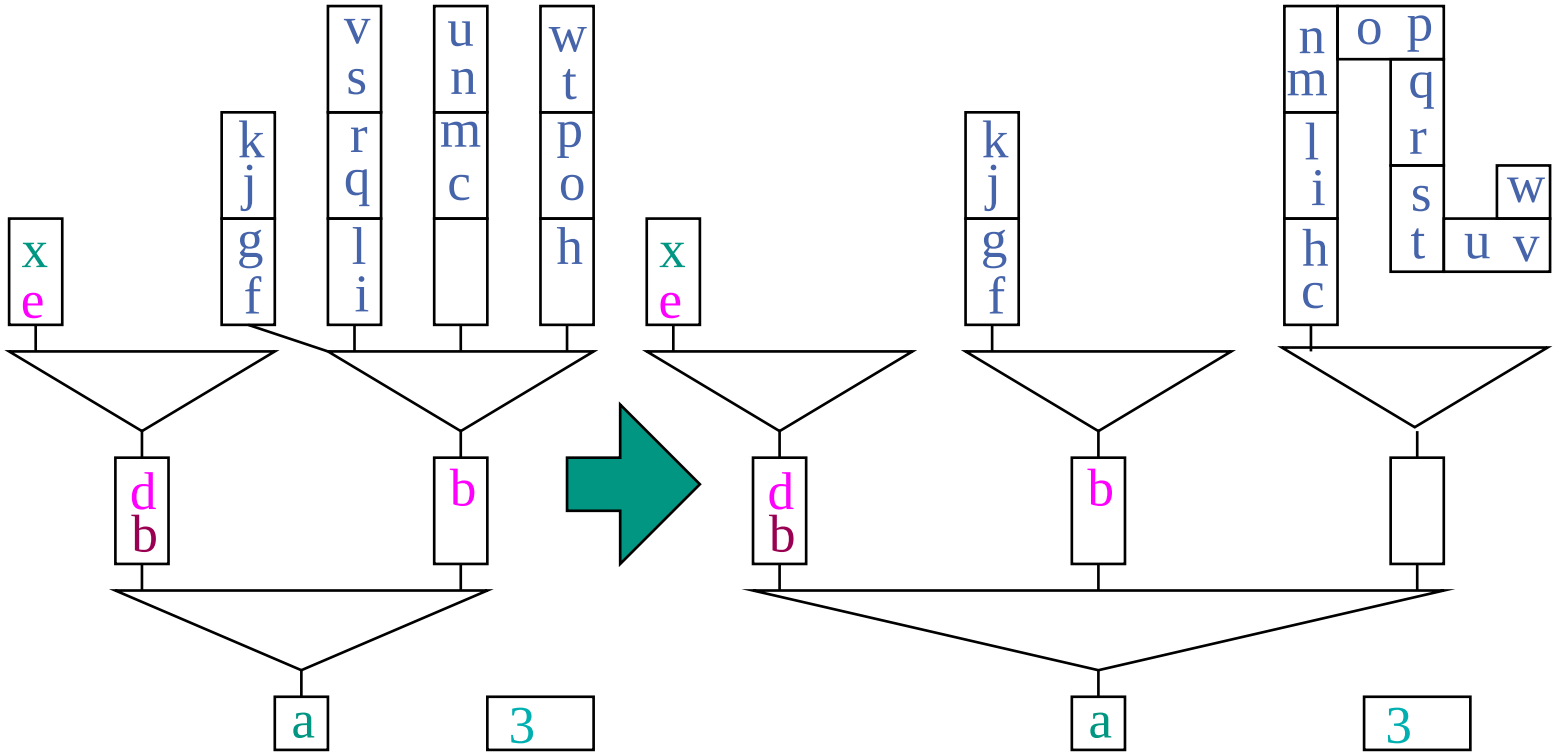
Example

Merge group 1



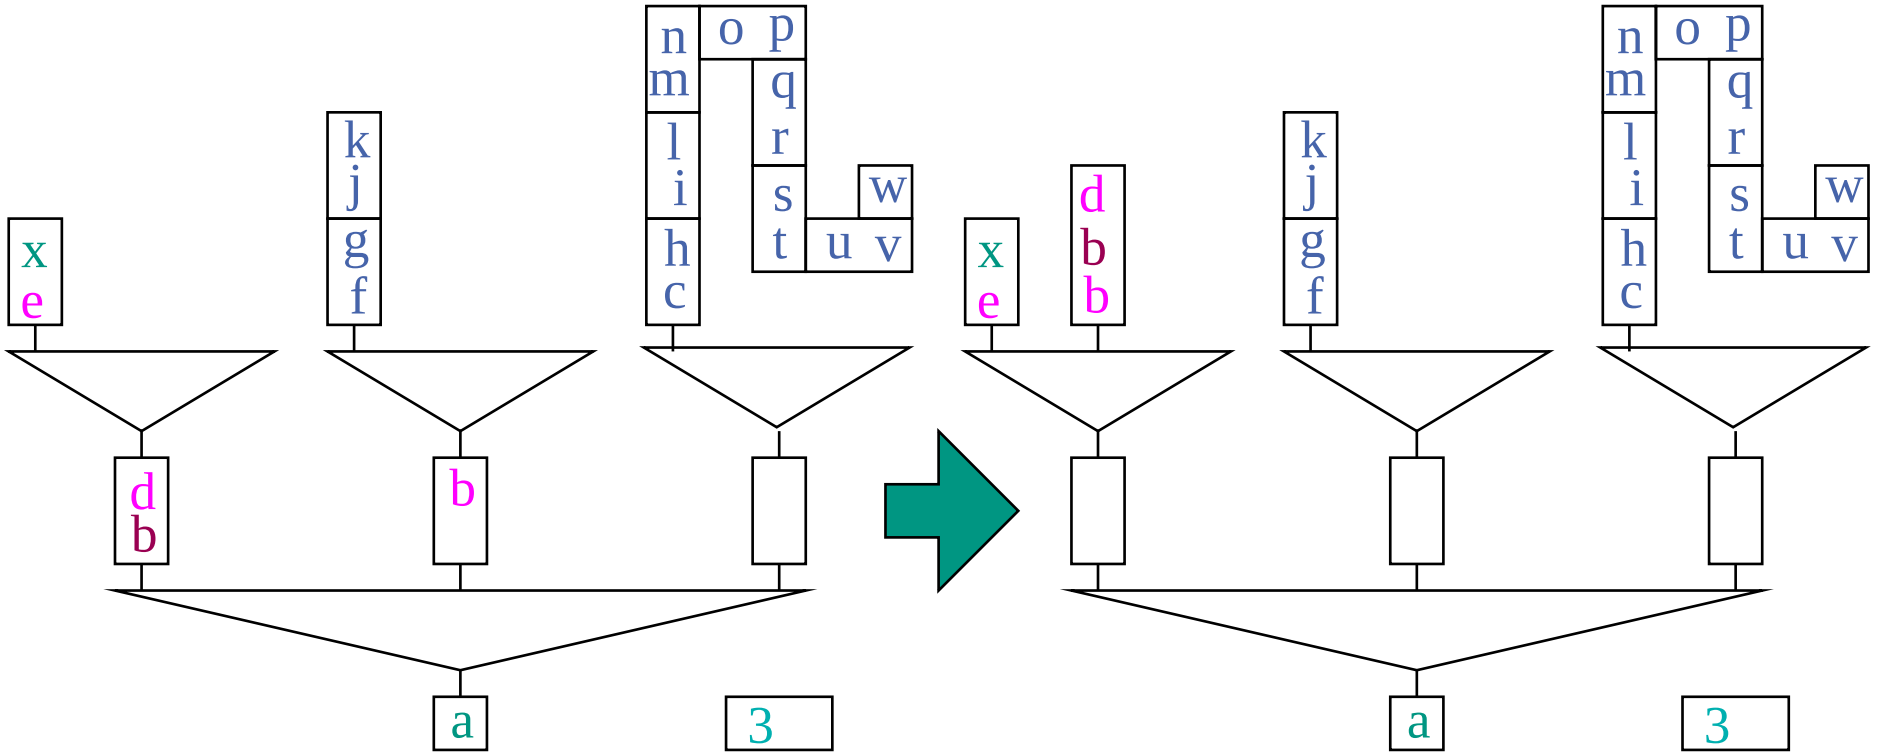
Example

Merge group 2



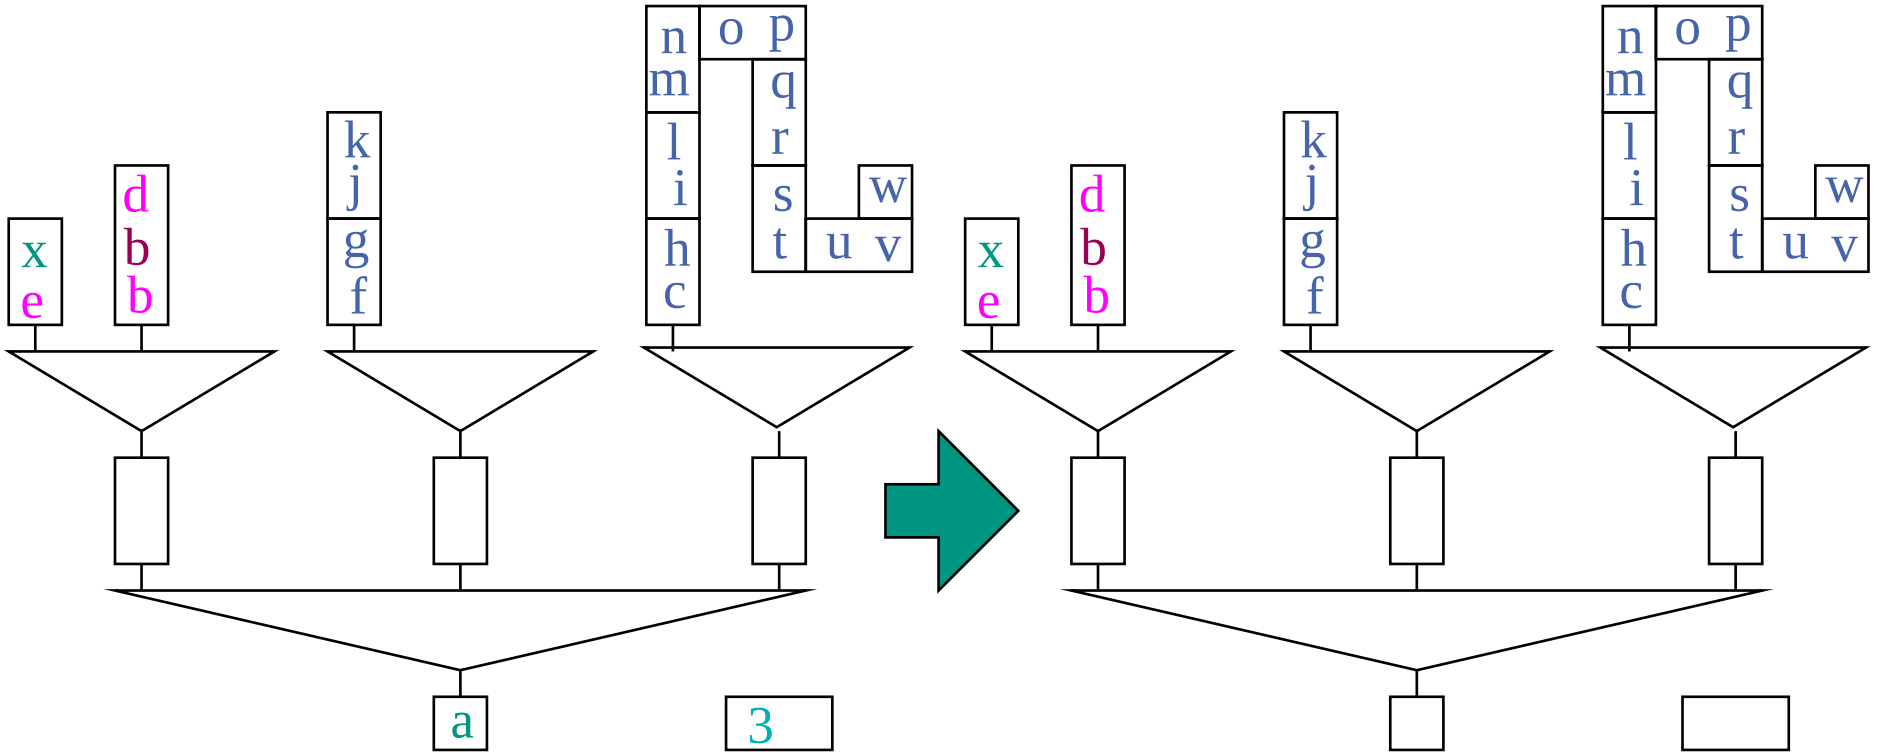
Example

Merge group buffers



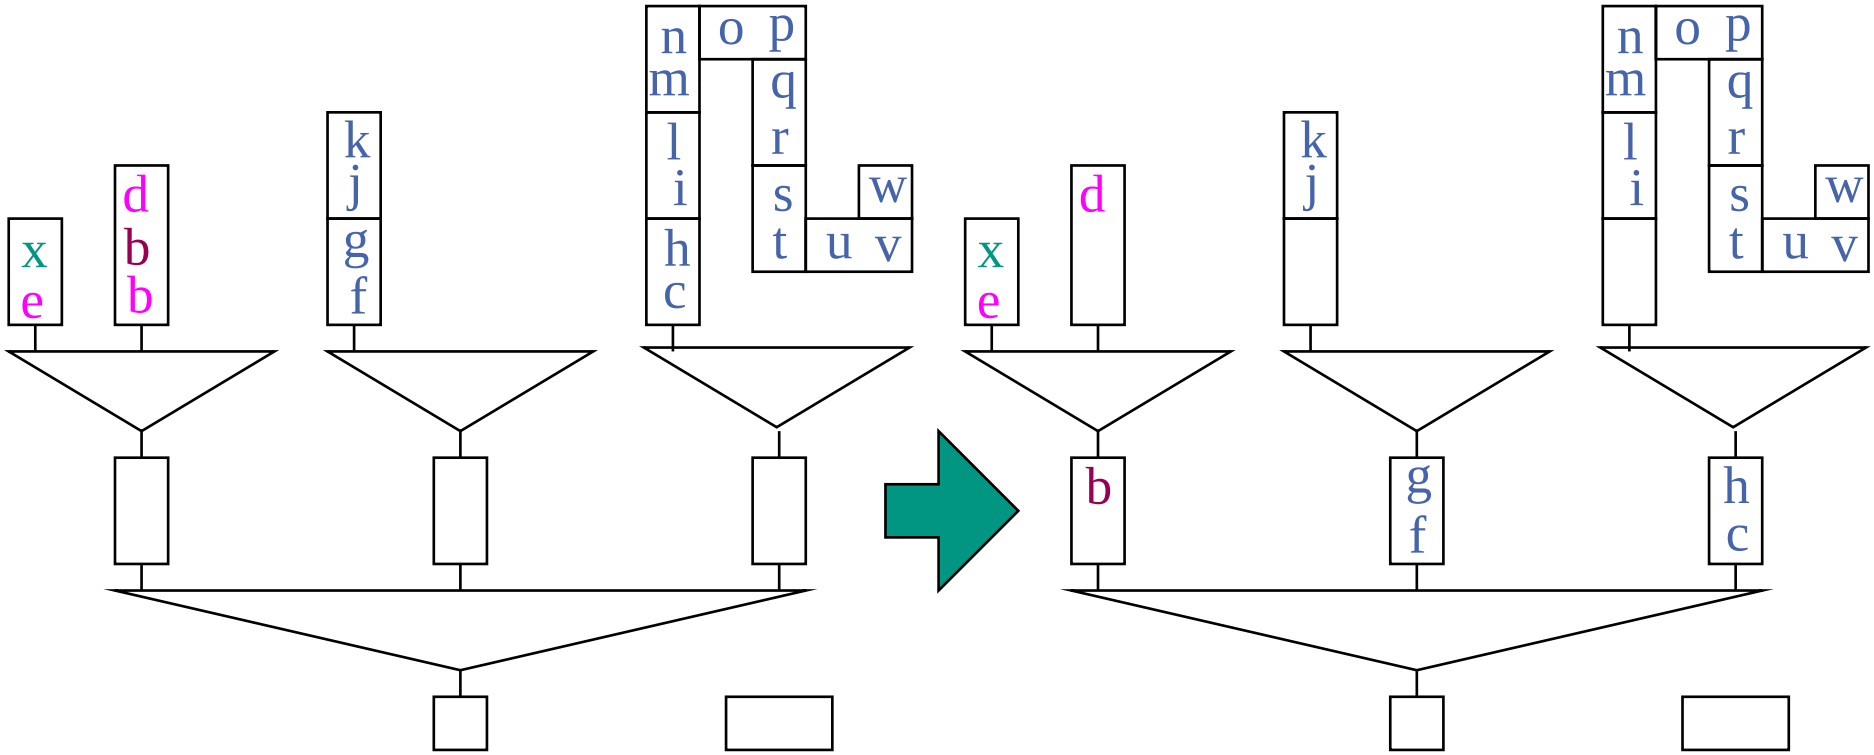
Example

DeleteMin $\rightsquigarrow$ 3; DeleteMin $\rightsquigarrow$ a;



Example

DeleteMin $\rightsquigarrow$ b



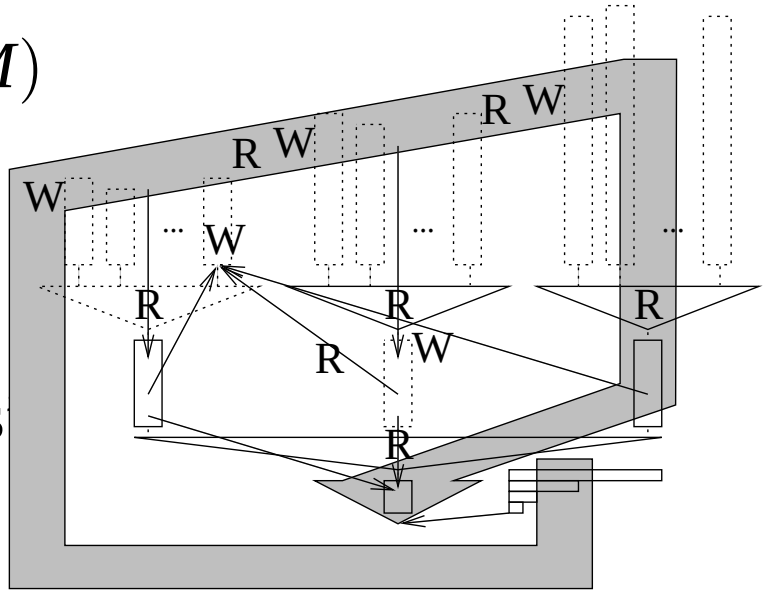
Analysis

- I insertions, buffer sizes $m = \Theta(M)$
- merging degree $k = \Theta(M/B)$

block accesses: $\text{sort}(I)$ + "small terms"

key comparisons: $I \log I$ + "small terms"

(on average)



Other (similar, earlier) [Arge 95, Brodal-Katajainen 98, Brengel et al. 99, Fadel et al. 97] data structures spend a factor ≥ 3 more I/Os to replace I by queue size.

Implementation Details

- Fast routines for 2–4 way merging keeping smallest elements in registers
- Use sentinels to avoid special case treatments (empty sequences, ...)
- Currently heap sort for sorting the insertion buffer
- $k \neq M/B$: multiple levels, limited associativity, TLB

Experiments

Keys: random 32 bit integers

Associated information: 32 dummy bits

Deletion buffer size: 32

Group buffer size: 256

Merging degree k: 128

Near optimal

: performance on

all machines tried!

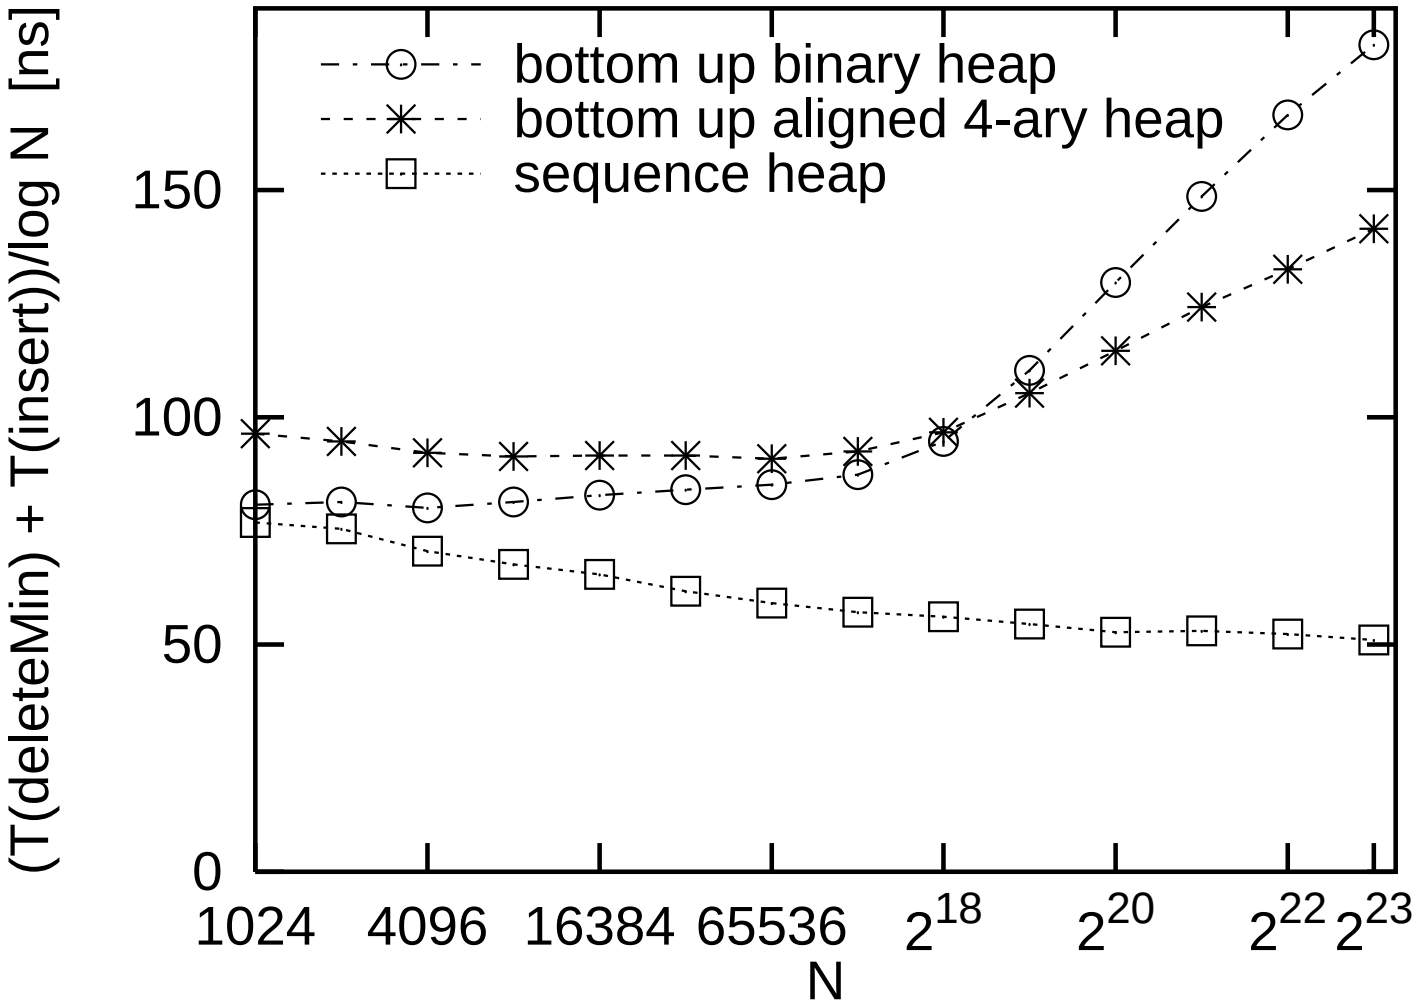
Compiler flags: Highly optimizing, nothing advanced

Operation Sequence:

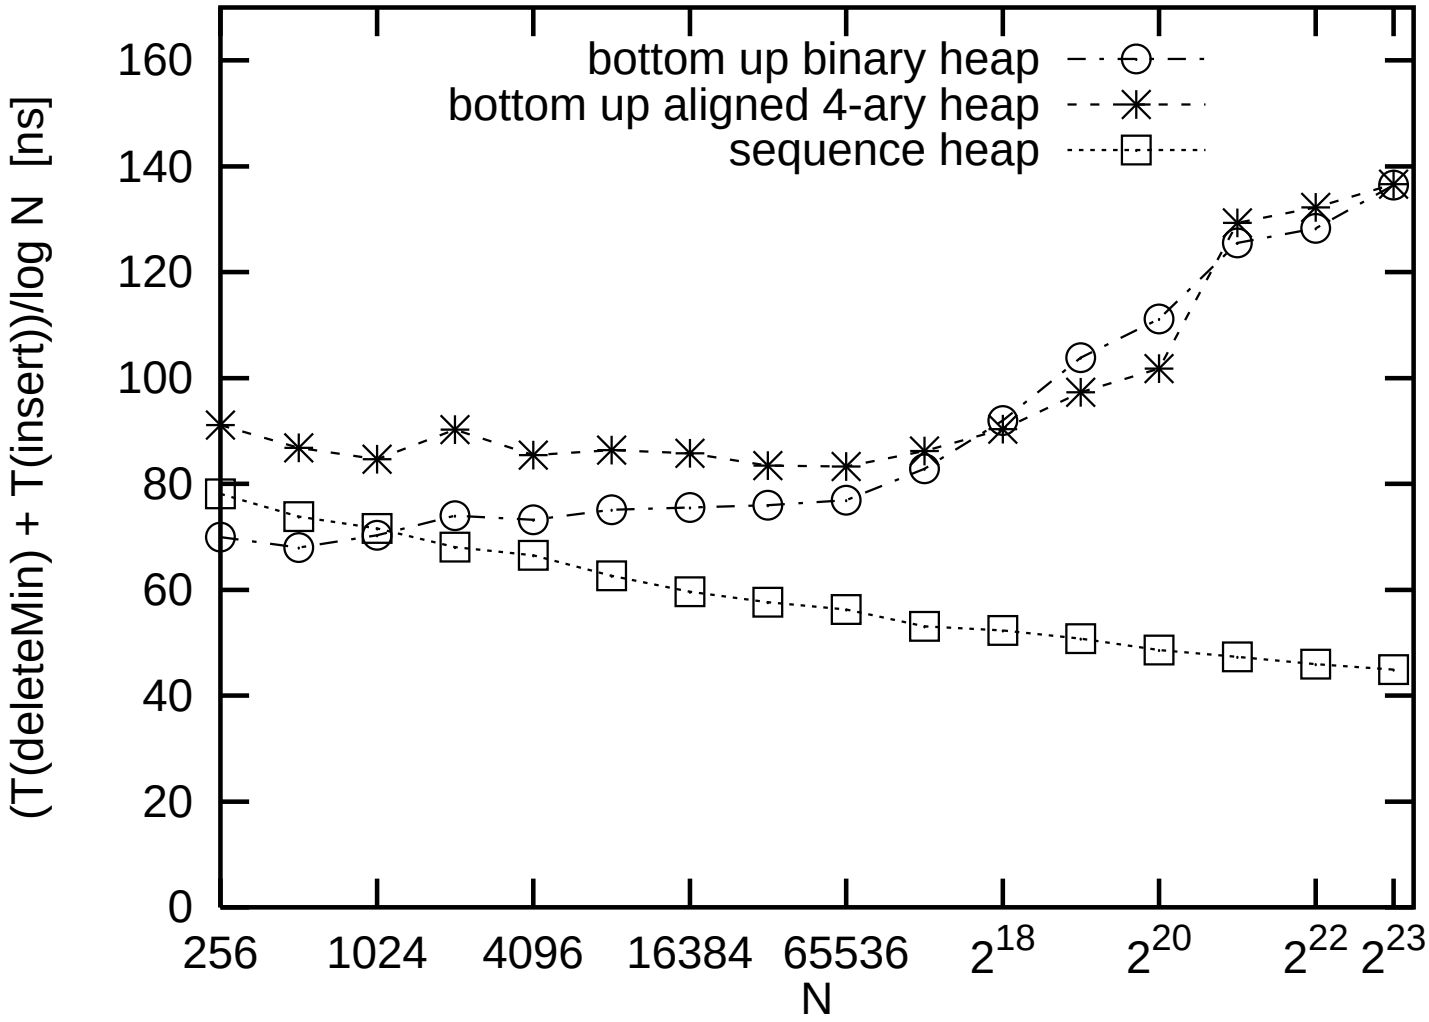
$$(\text{Insert-DeleteMin-Insert})^N\,(\text{DeleteMin-Insert-DeleteMin})^N$$

Near optimal performance on all machines tried!

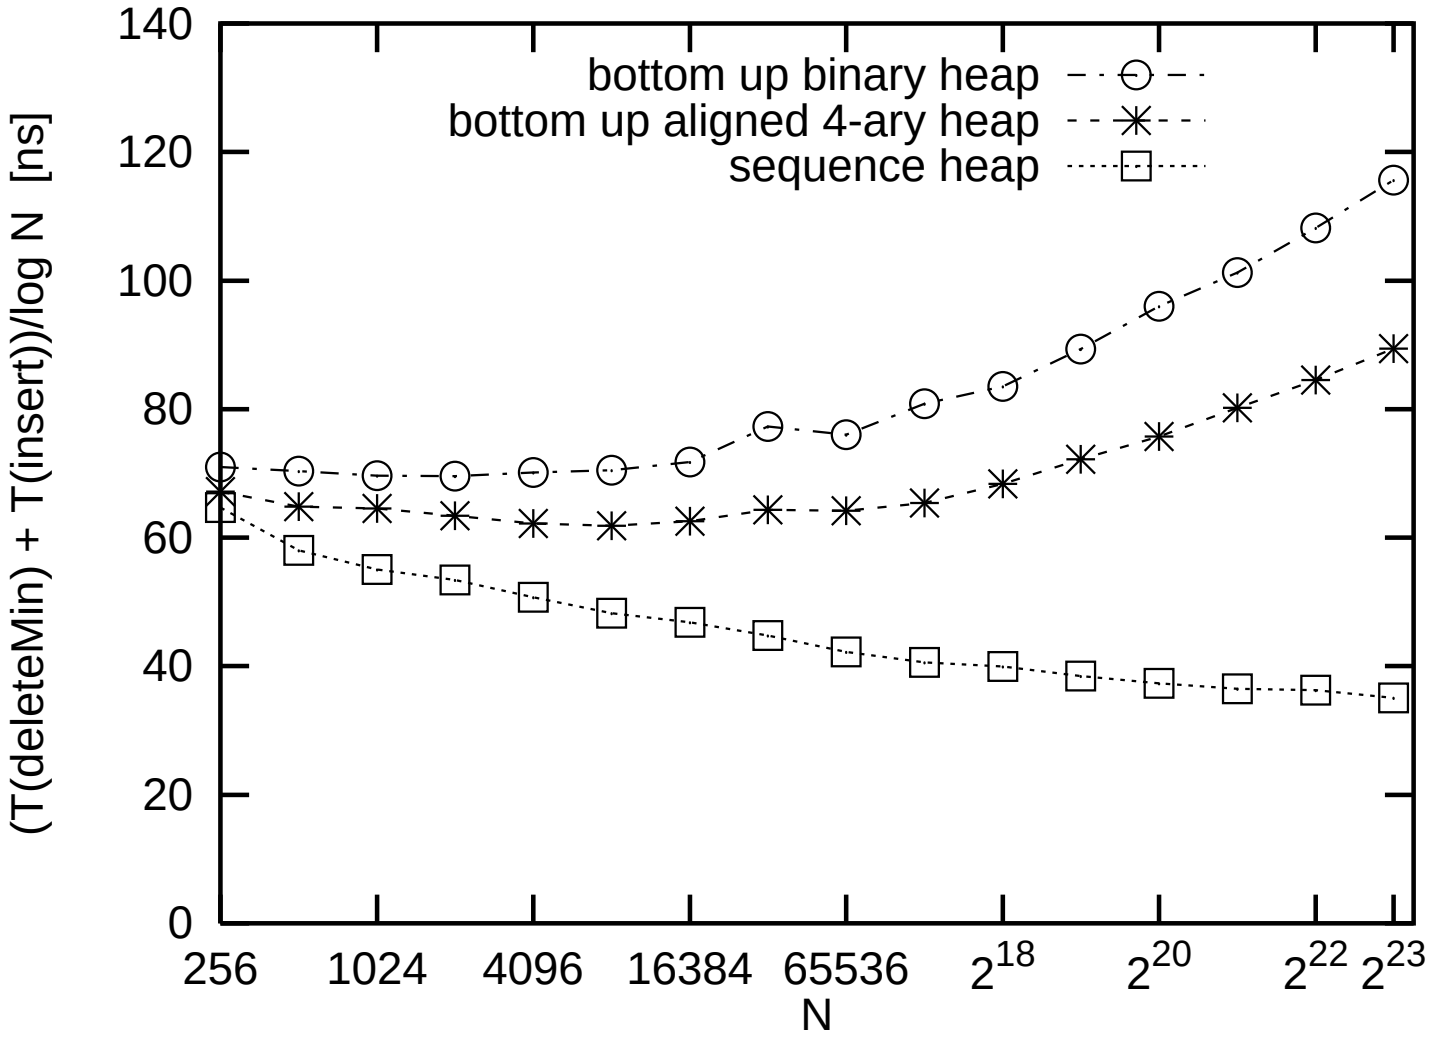
MIPS R10000, 180 MHz



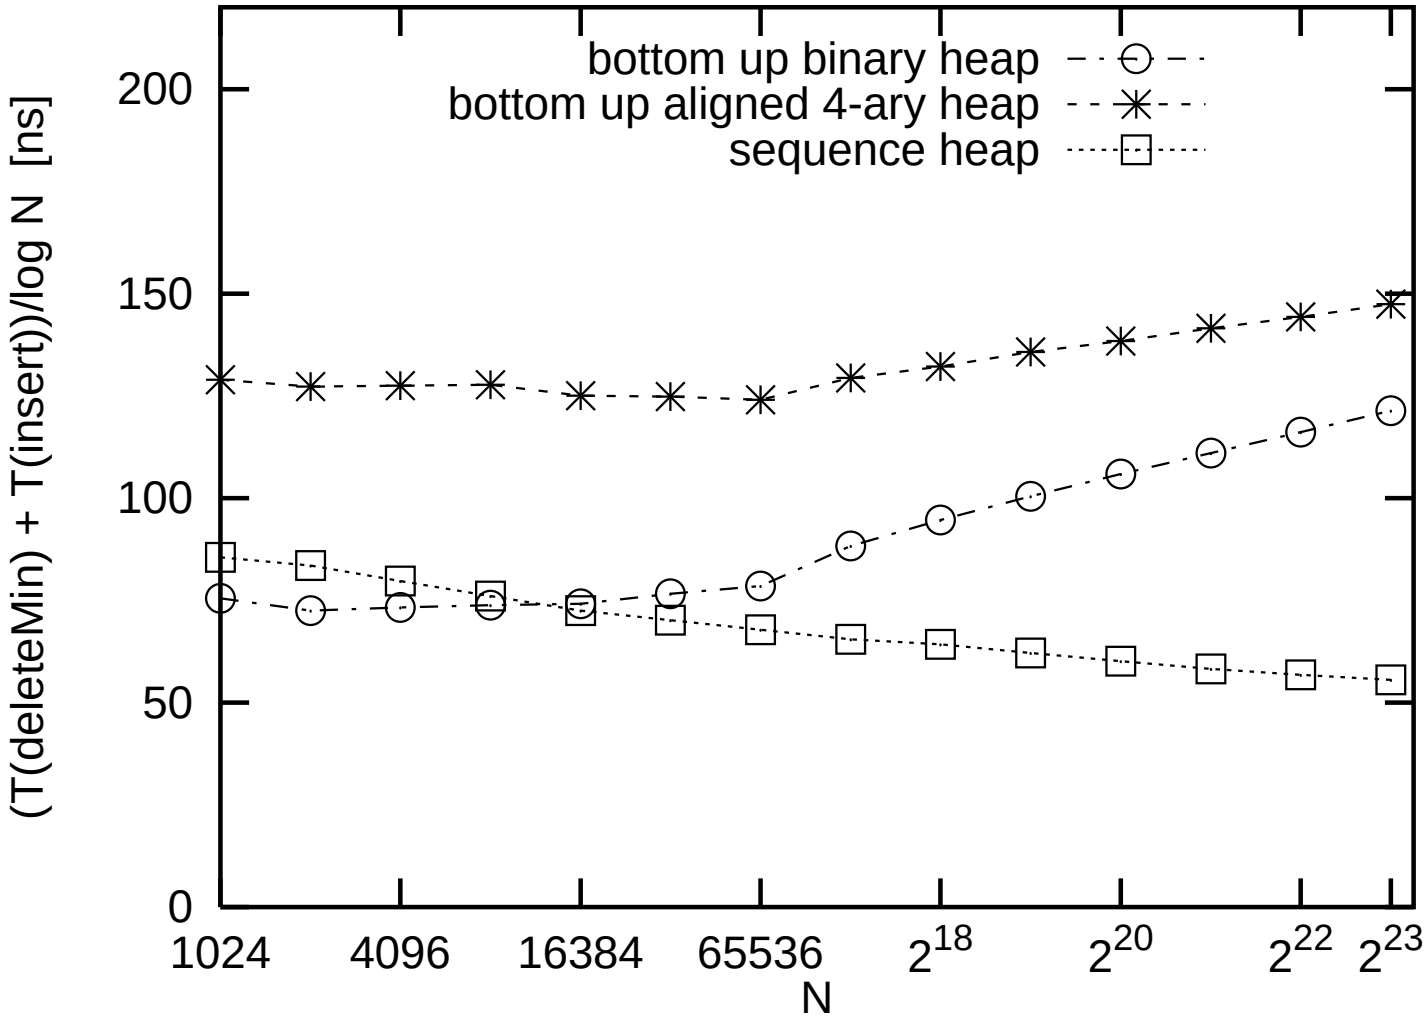
Ultra-SparcIIi, 300 MHz



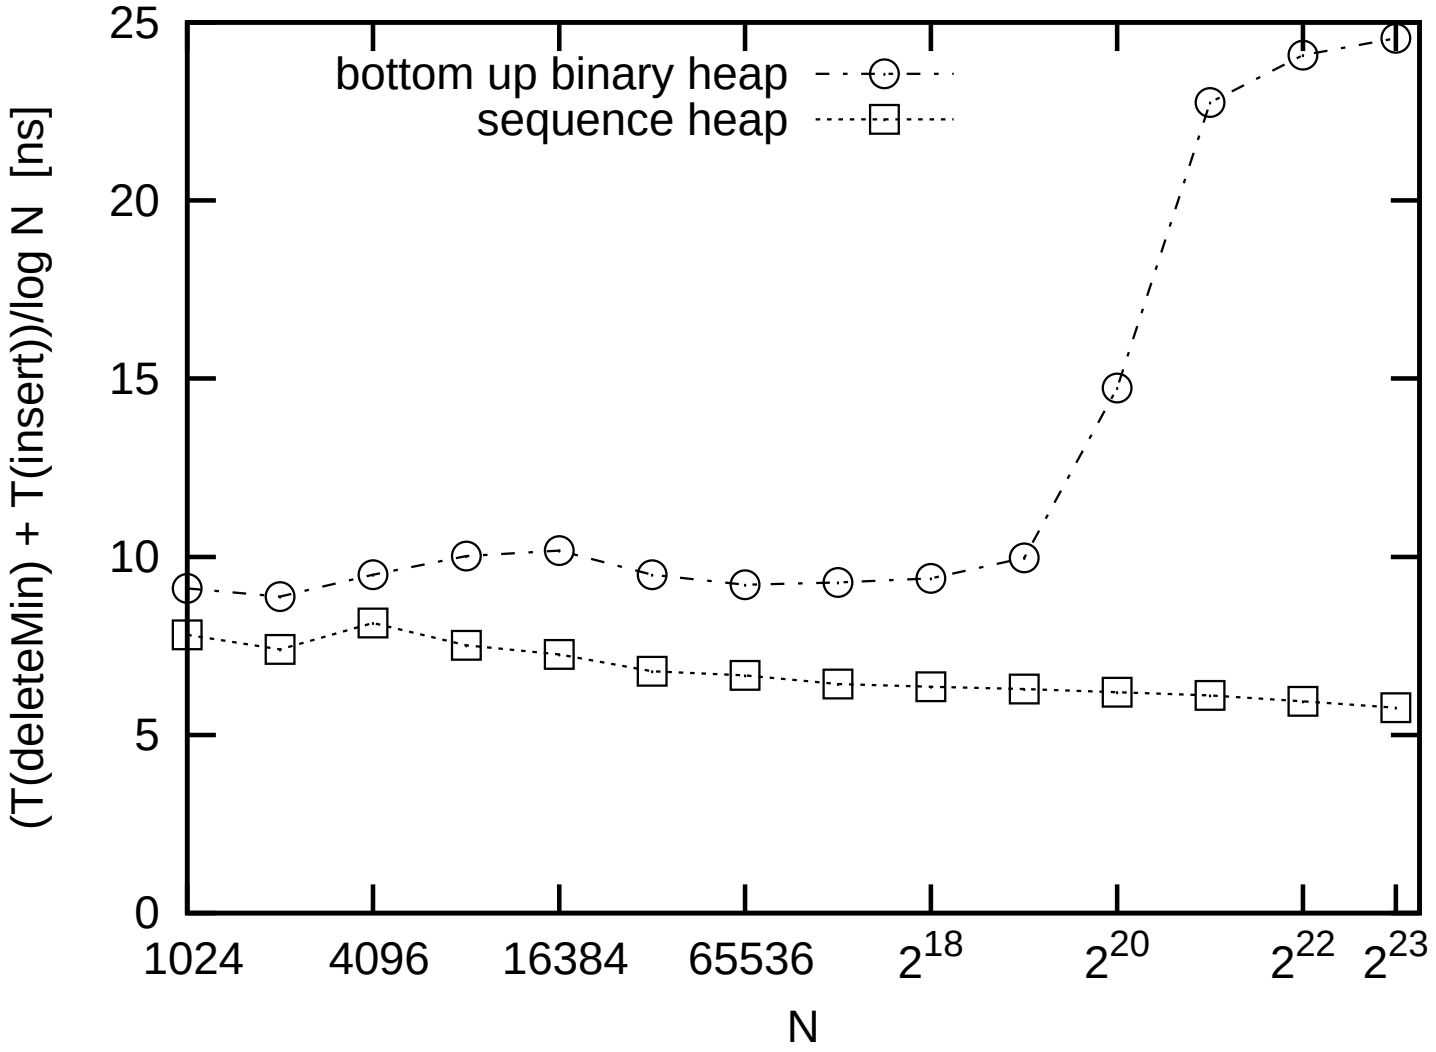
Alpha-21164, 533 MHz



Pentium II, 300 MHz

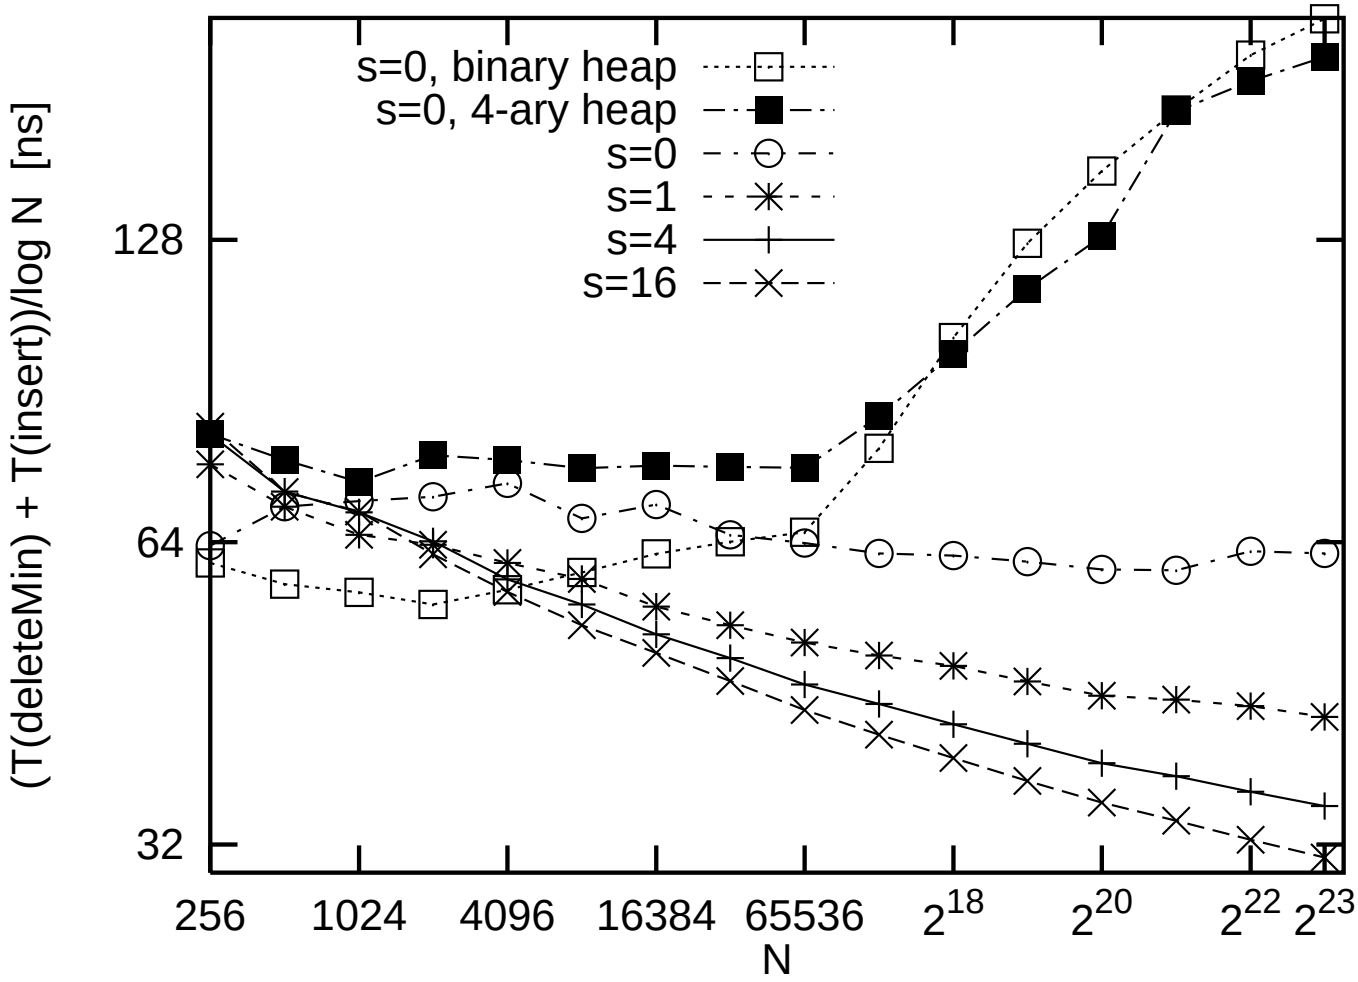


Core2 Duo Notebook, 1.??? GHz



$$(\text{insert}\ (\text{deleteMin insert})^s)^N$$

$$(\text{deleteMin}\ (\text{insert deleteMin})^s)^N$$



Methodological Lessons

If you want to compare small constant factors in execution time:

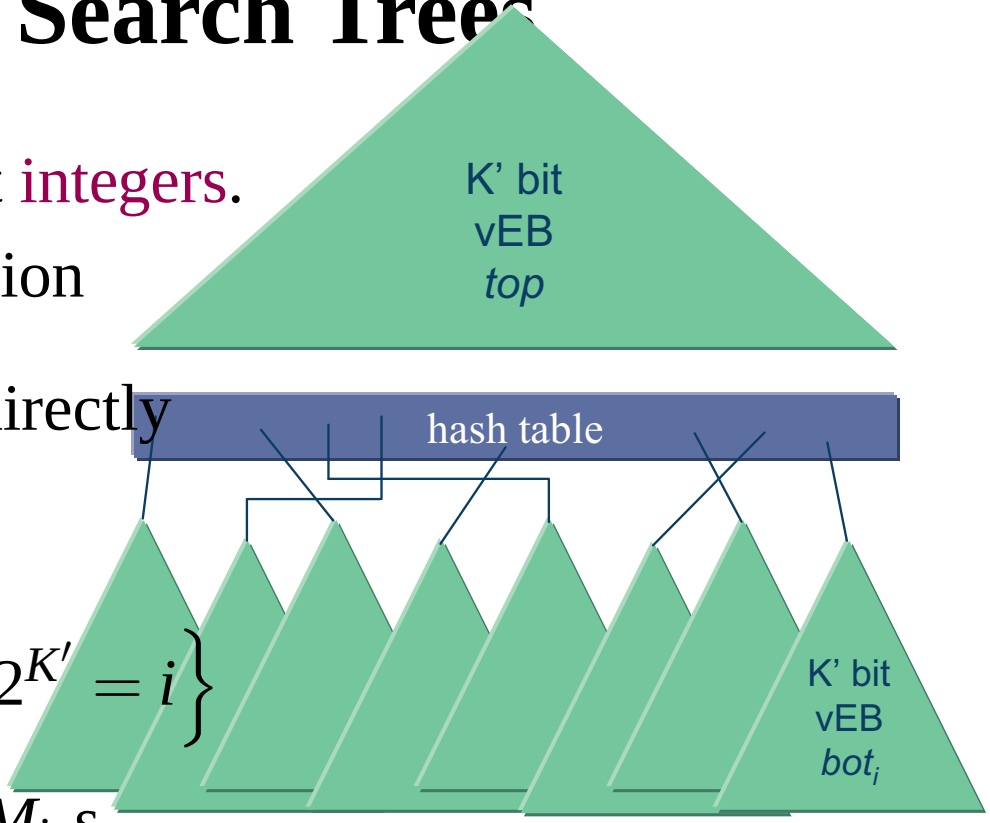
- Reproducability demands publication of source codes
  (4-ary heaps, old study in Pascal)
- Highly tuned codes in particular for the competitors
  (binary heaps have factor 2 between good and naive implementation).
  How do you compare two mediocre implementations?
- Careful choice/description of inputs
- Use multiple different hardware platforms
- Augment with theory (e.g., comparisons, data dependencies, cache faults, locality effects . . .)

Open Problems

- Dependence on size rather than number of insertions
- Parallel disks
- Space efficient implementation
- Multi-level cache aware or cache-oblivious variants

3 van Emde-Boas Search Trees

- Store set M of $K = 2^k$-bit integers.
  later: associated information
- $K = 1$ or $|M| = 1$: store directly
- $K' := K/2$
- $M_i := \left\{ x \bmod 2^{K'} : x \textbf{ div } 2^{K'} = i \right\}$
- root points to nonempty M_i-s
- top $t = \{i : M_i \neq \emptyset\}$
- insert, delete, search in $\mathcal{O}(\log K)$ time



Locate

$//\min x \in M : y \leq x$

Function locate$(y : \mathbb{N}) :$ ElementHandle

  if $y > \max M$ **then return** ∞

  if $K = 1$ **then return** locateLocally(y)

  if $M = \{x\}$ **then return** x

  $i := y$ **div** $2^{K/2}$

  if $M_i = \emptyset \vee y > \max M_i$ **then**

    return $\min M_{\text{top.locate}(i)}$

  else

    return $i2^{K/2} + M_i$.locate$(y \bmod 2^{K/2})$

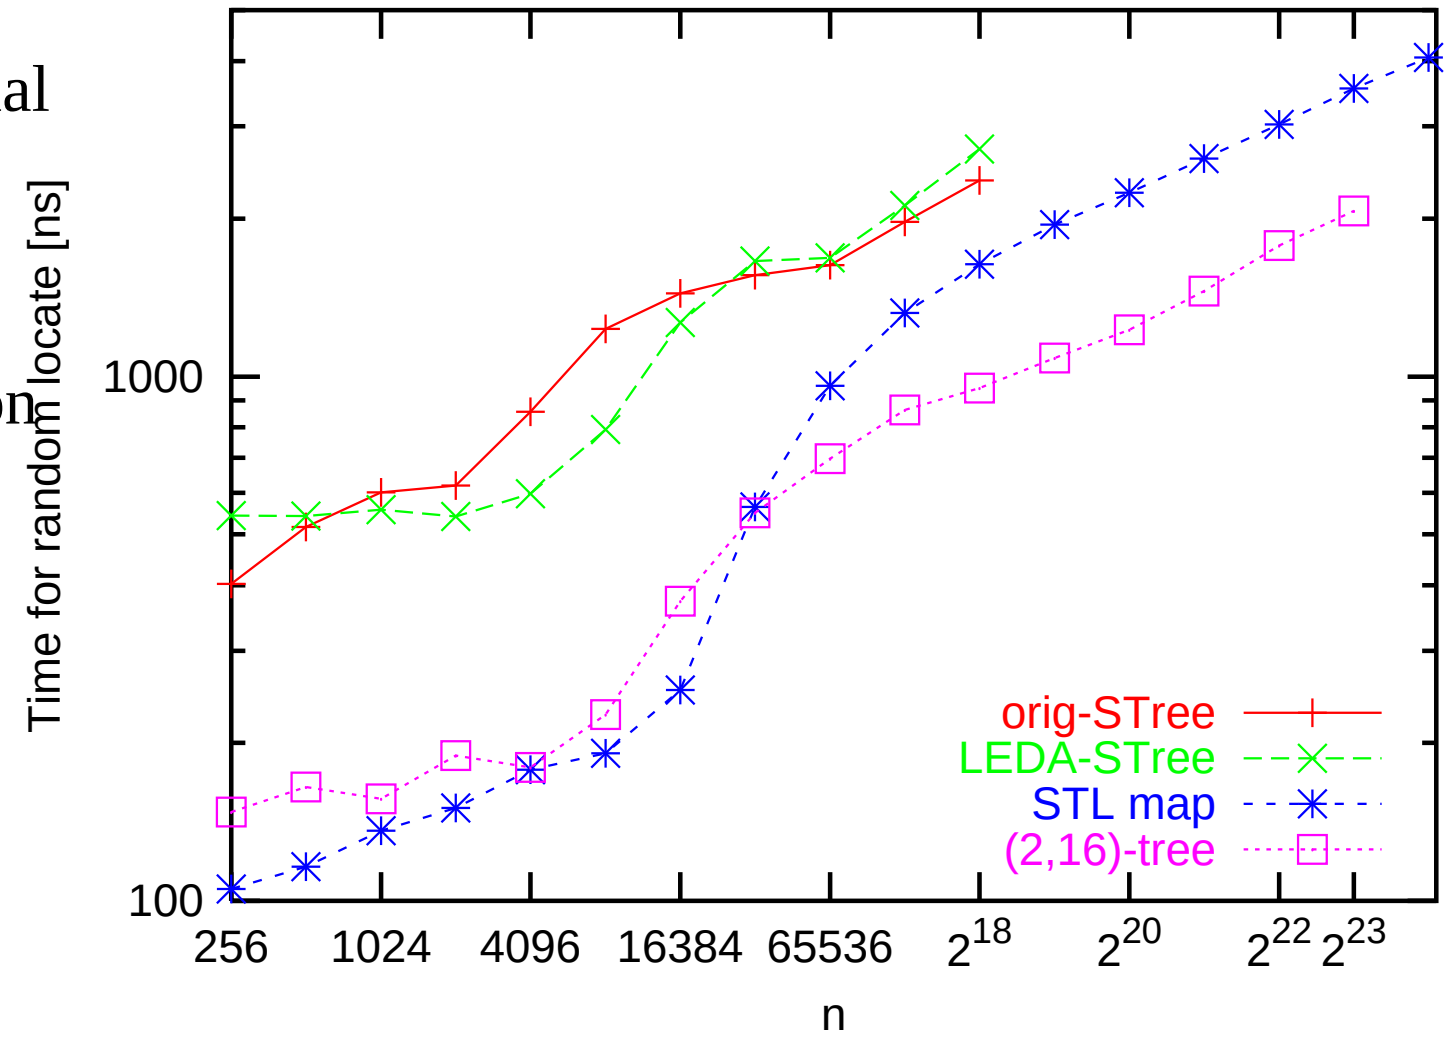
Comparison with Comparison Based Search Trees

Ideally: $\log n \rightsquigarrow \log\log n$

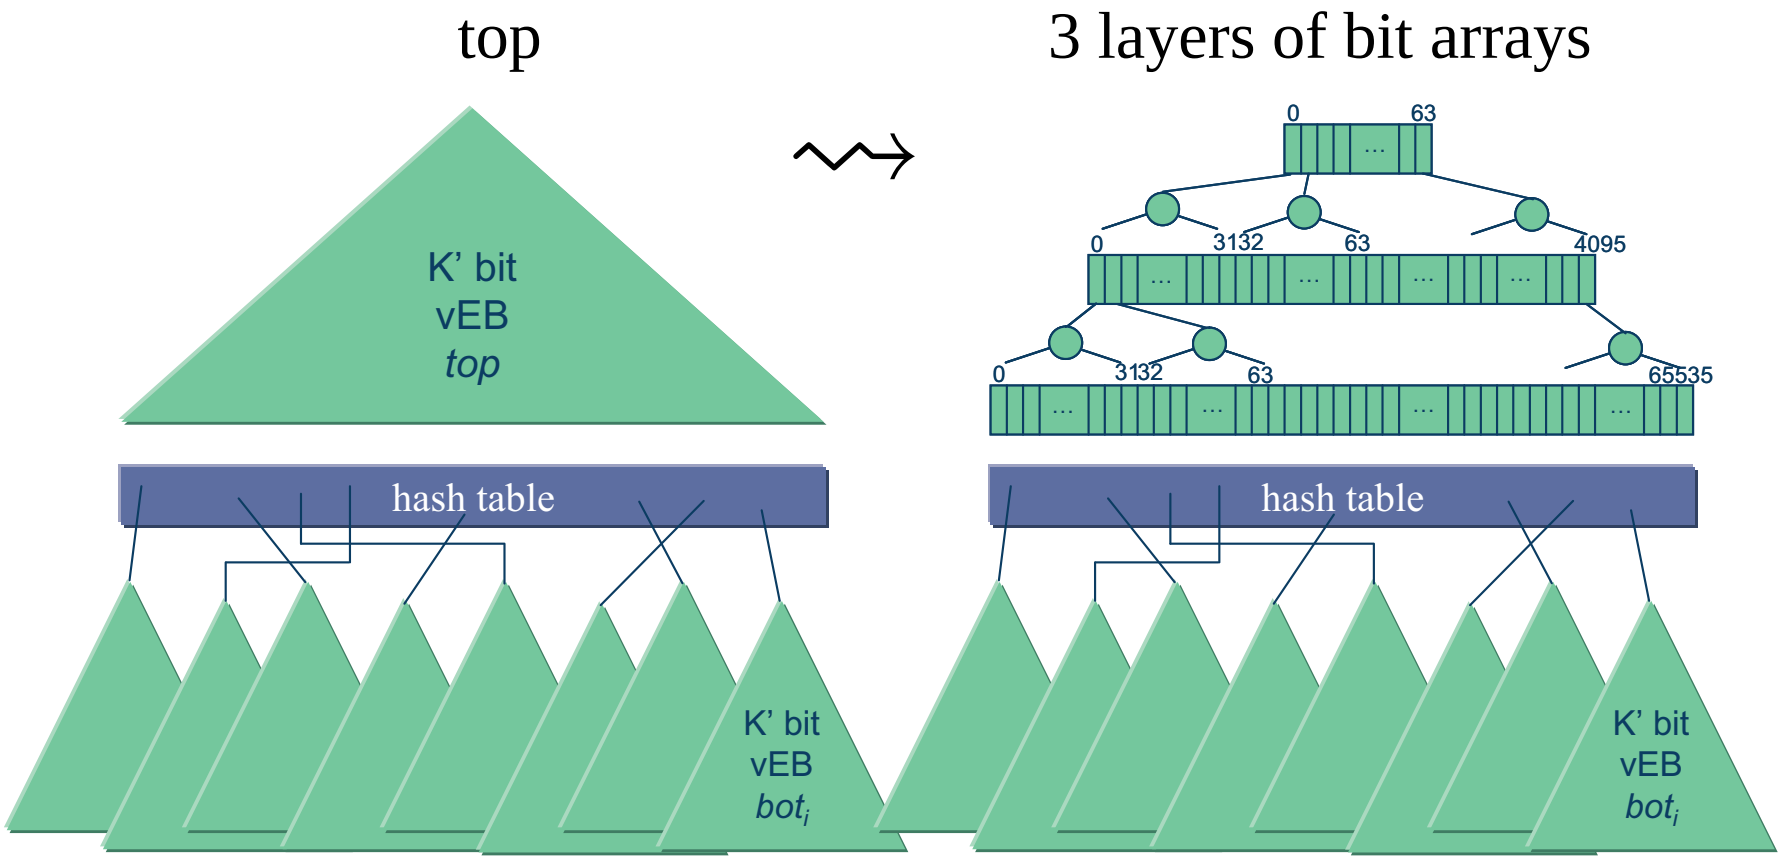
Problems:

Many special case tests

High space consumption



Efficient 32 bit Implementation

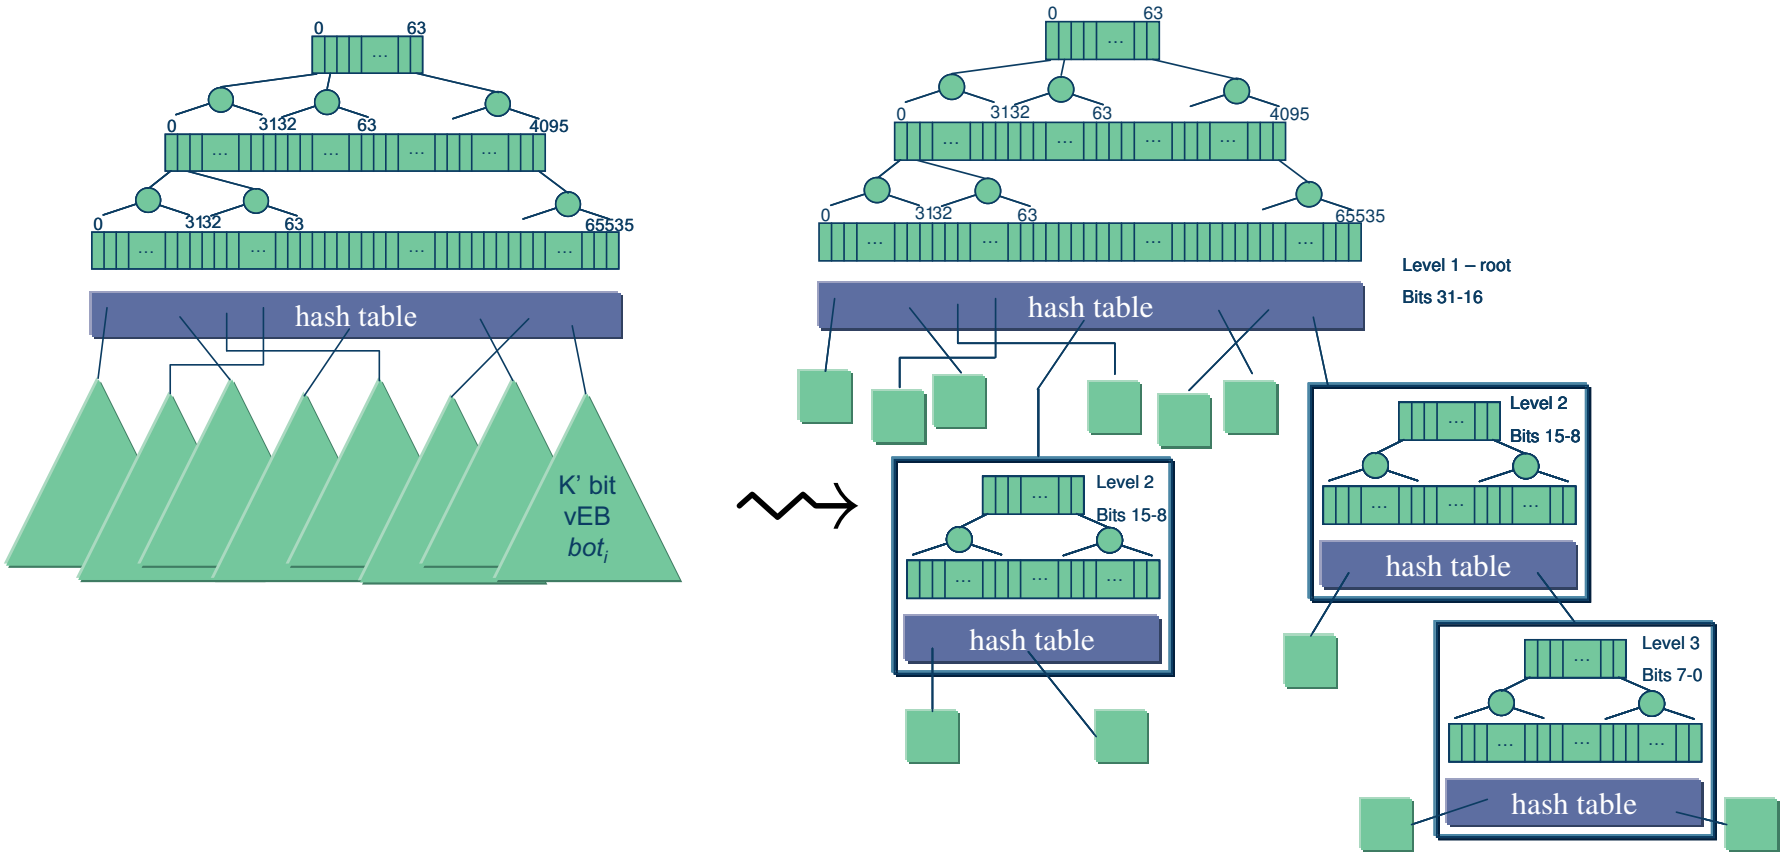


Layers of Bit Arrays

$$t^1[i] = 1 \text{ iff } M_i \neq \emptyset$$
$$t^2[i] = t^1[32i] \vee t^1[32i+1] \vee \cdots \vee t^1[32i+31]$$
$$t^3[i] = t^2[32i] \vee t^2[32i+1] \vee \cdots \vee t^2[32i+31]$$

Efficient 32 bit Implementation

Break recursion after 3 layers



Efficient 32 bit Implementation

Element List

Locate High Level

// return handle of $\min x \in M : y \leq x$

Function locate$(y : \mathbb{N}) :$ ElementHandle

if $y > \max M$ **then return** ∞

$i := y[16..31]$ // Level 1

if $r[i] = \text{nil} \vee y > \max M_i$ **then return** $\min M_{t^1}$.locate(i)

if $M_i = \{x\}$ **then return** x

$j := y[8..15]$ // Level 2

if $r_i[j] = \text{nil} \vee y > \max M_{ij}$ **then return** $\min M_{i,t_i^1}$.locate(j)

if $M_{ij} = \{x\}$ **then return** x

return $r_{ij}[t_{ij}^1$.locate$(y[0..7])]$ // Level 3

Locate in Bit Arrays

// find the smallest $j \geq i$ such that $t^k[j] = 1$

Method locate(i) for a bit array t^k consisting of n bit words

// $n = 32$ for $t^1, t^2, t^1_i, t^1_{ij}$; $n = 64$ for t^3; $n = 8$ for t^2_i, t^2_{ij}

assert some bit in t^k to the right of i is nonzero

$j := i$ **div** n // which word?

$a := t^k[nj..nj+n-1]$

set $a[(i \bmod n)+1..n-1]$ to zero // $n-1 \cdots i \bmod n \cdots 0$

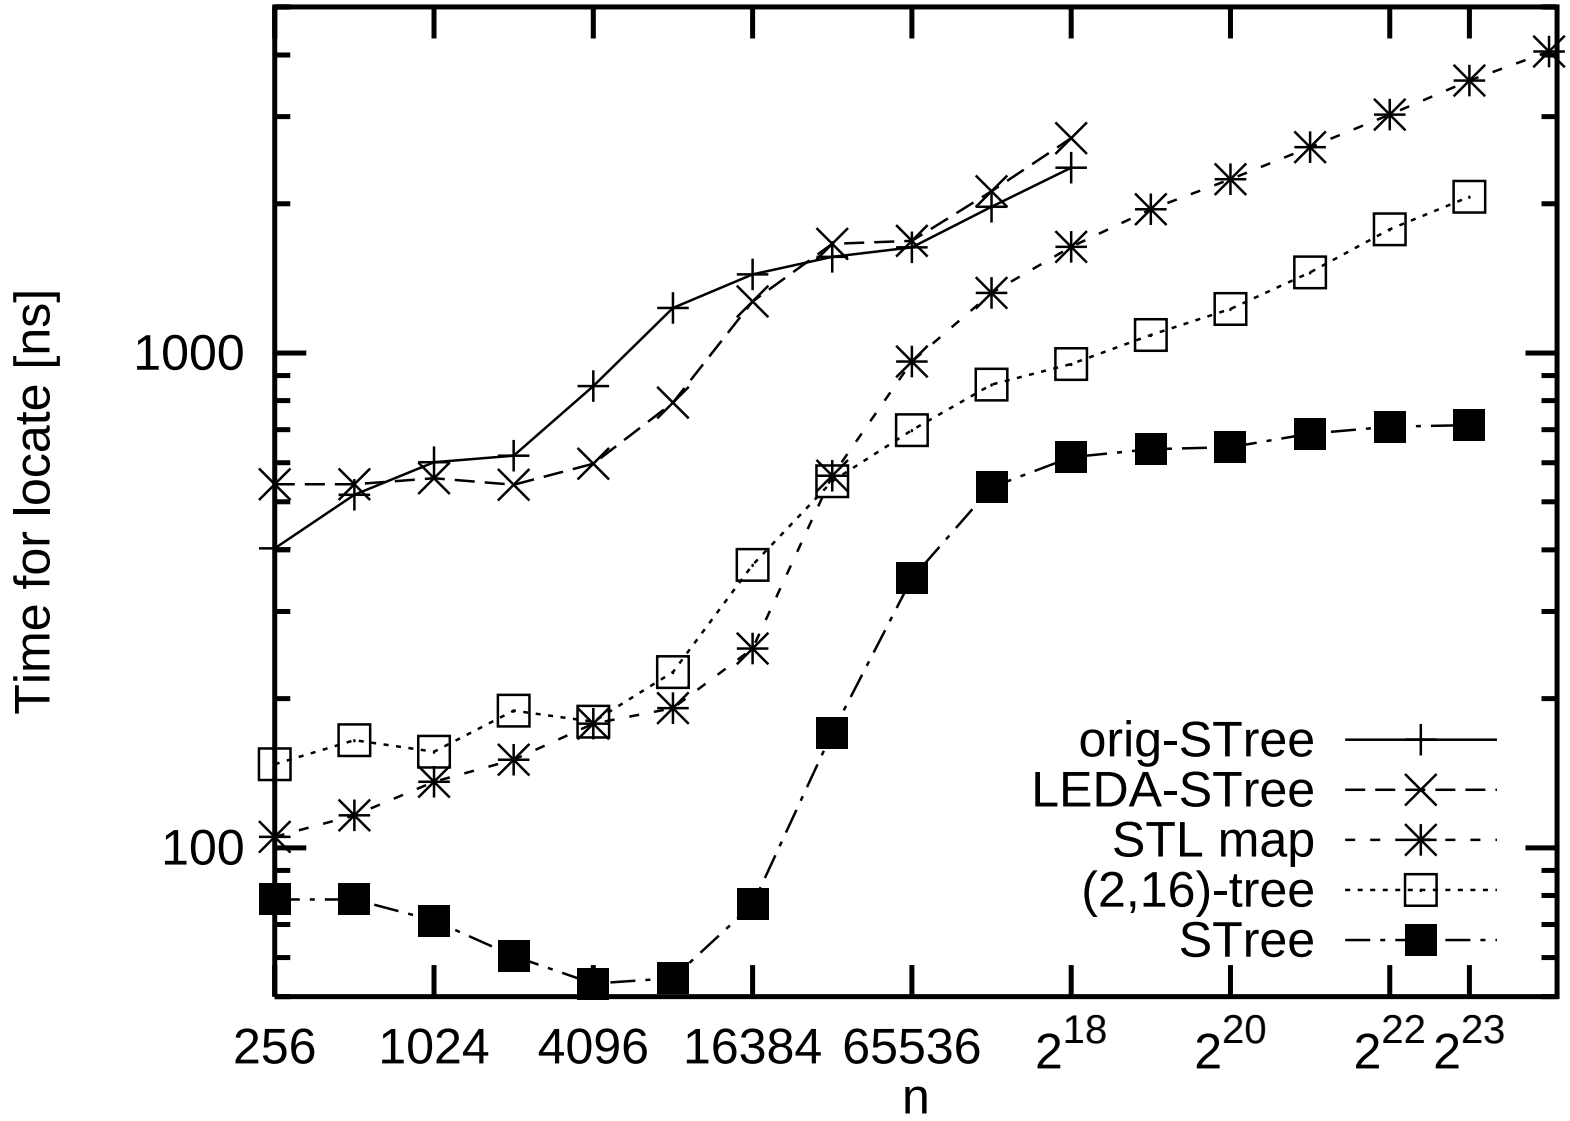
if $a = 0$ **then**

$j := t^{k+1}$.locate(j)

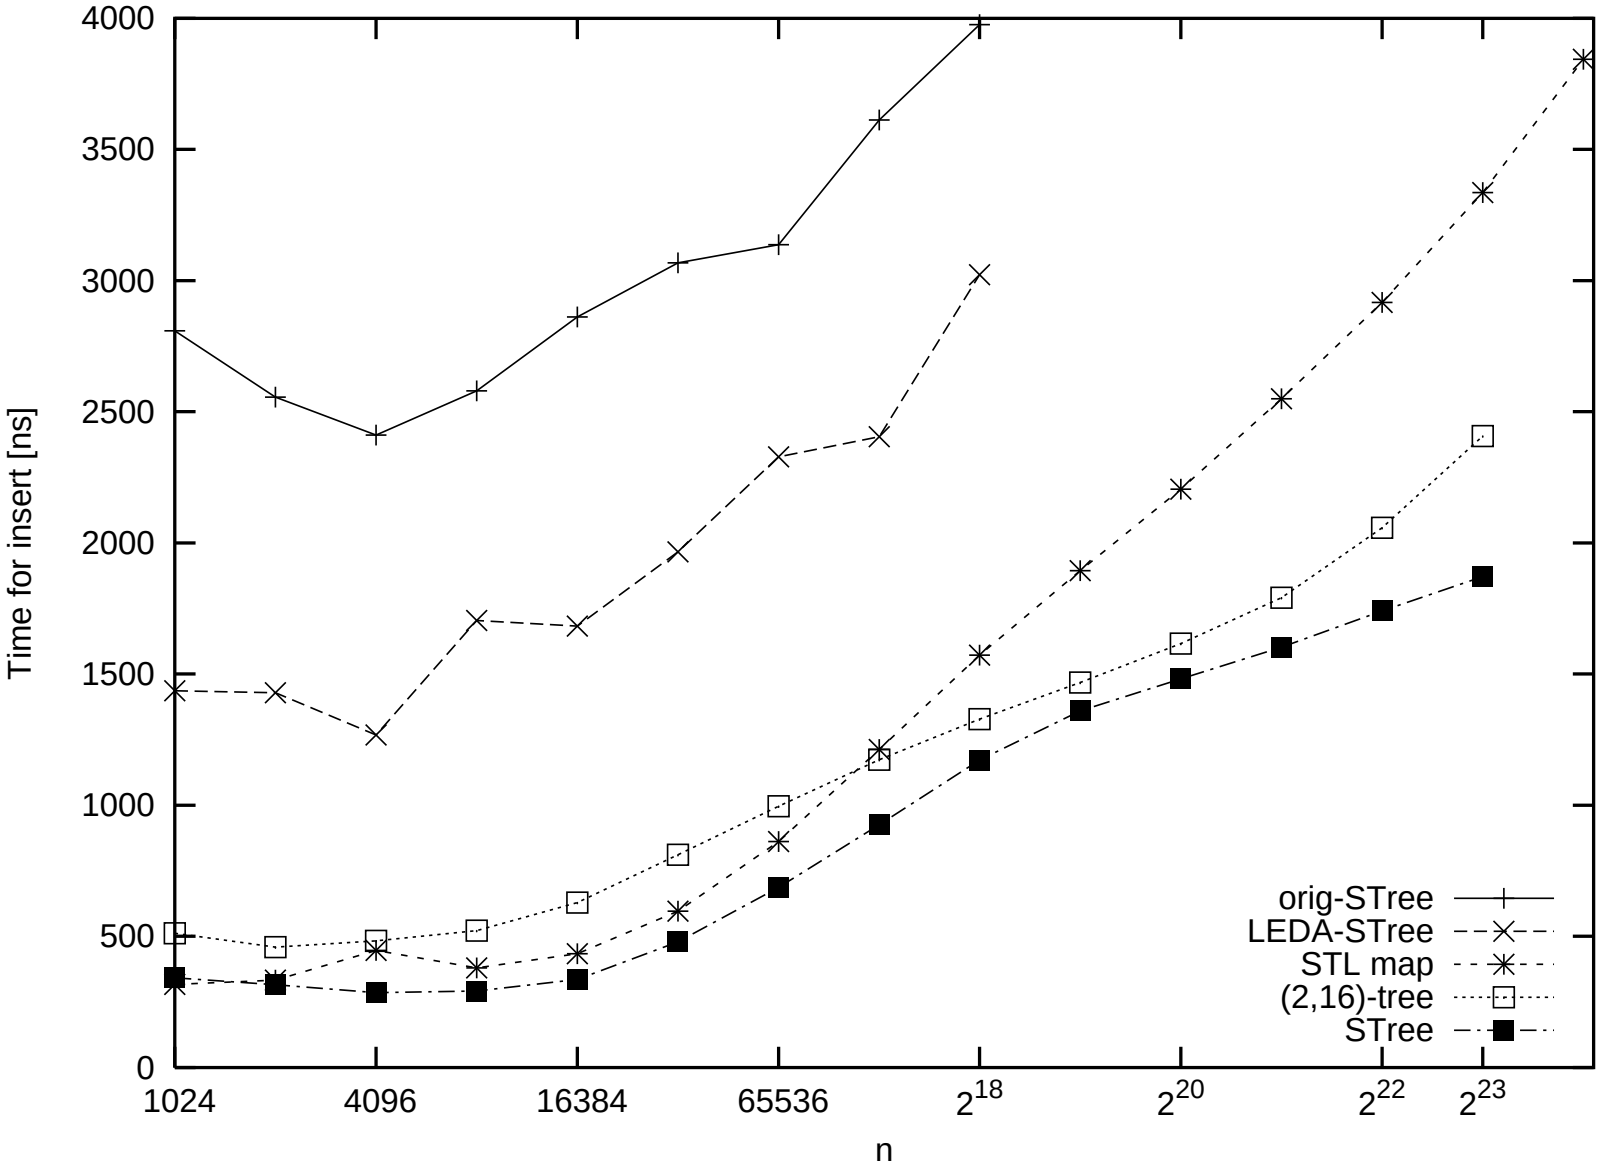
$a := t^k[nj..nj+n-1]$

return $nj +$ msbPos(a) // e.g. floating point conversion

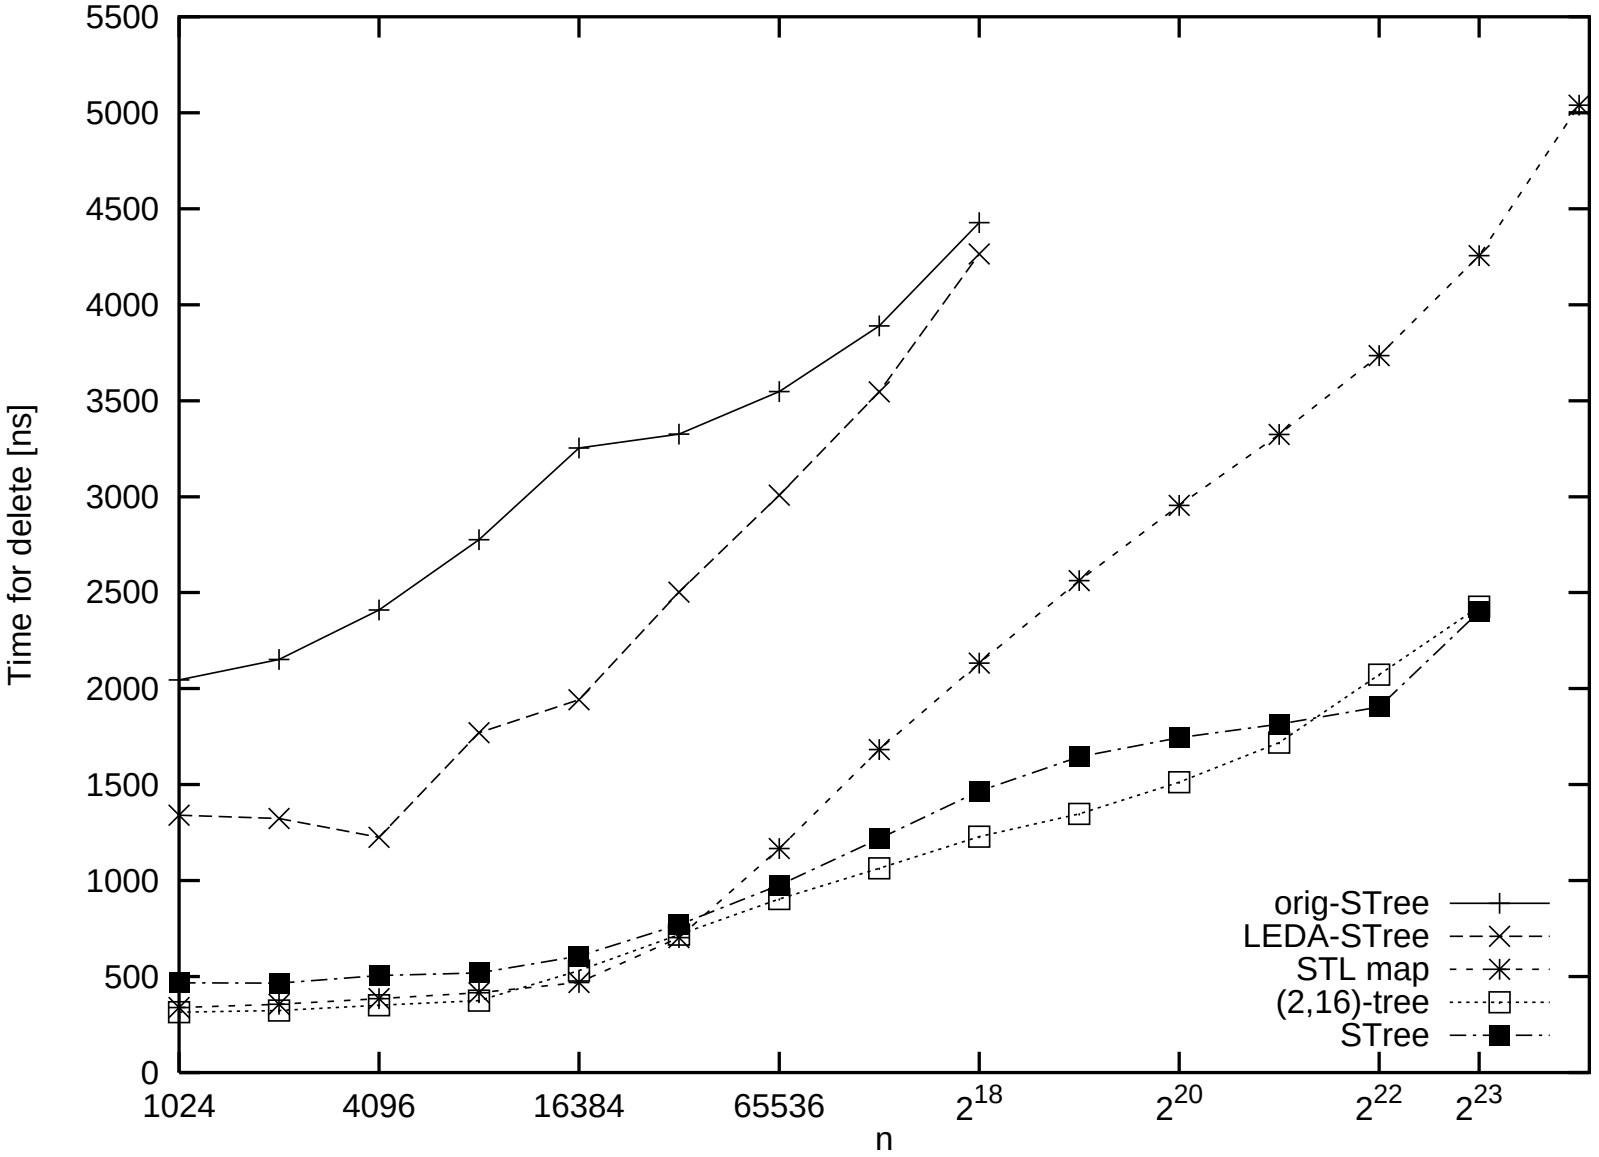
Random Locate



Random Insert



Delete Random Elements



Open Problems

- Measurement for “worst case” inputs
- Measure Performance for realistic inputs
  - IP lookup etc.
  - Best first heuristics like, e.g., bin packing
- More space efficient implementation
- (A few) more bits

4 Hashing

"to hash" $\approx$ "to bring into complete disorder"

paradoxically, this helps us to find things more easily!

store set $M \subseteq$ Element.

key(e) is unique for $e \in M$.

support dictionary operations in $\mathcal{O}(1)$ time:

M.insert$(e :$ Element$)$: $M := M \cup \{e\}$

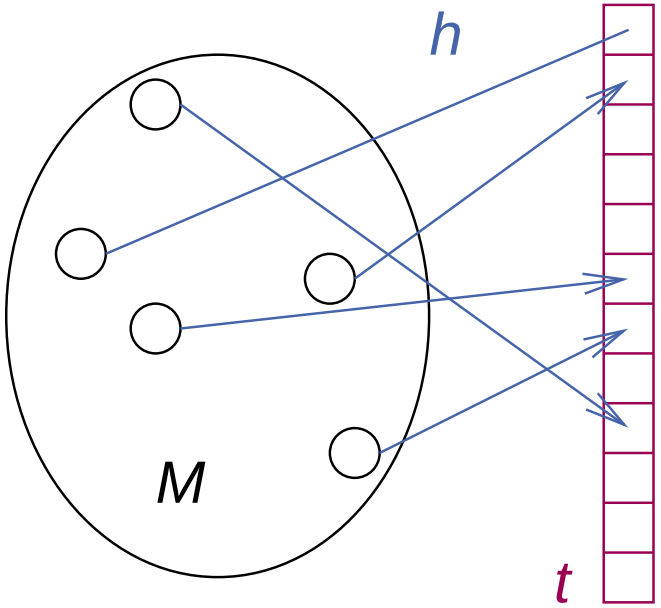
M.remove$(k :$ Key$)$: $M := M \setminus \{e\}, e = k$

M.find$(k :$ Key$)$: return $e \in M$ with $e = k$; $\perp$ if none present

(Convention: key is implicit), e.g. $e = k$ iff key$(e) = k$)

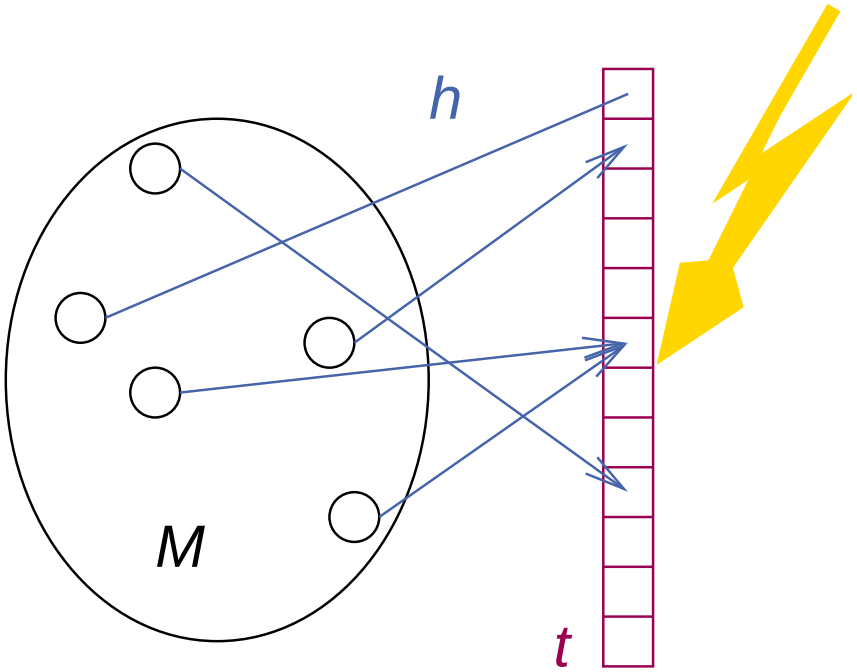
An (Over)optimistic approach

A (perfect) hash function h
maps elements of M to
unique entries of table $t[0..m-1]$, i.e.,
$t[h(\mathsf{key}(e))] = e$



Collisions

perfect hash functions are difficult to obtain

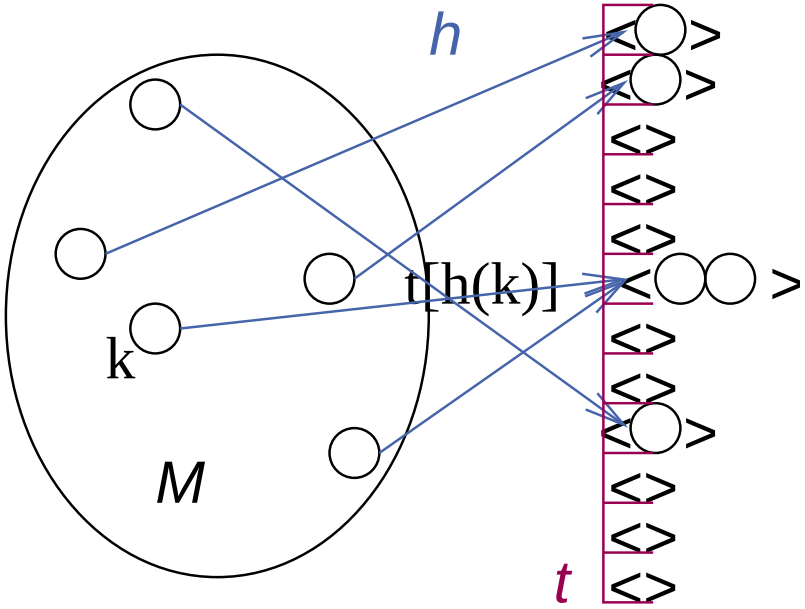


Example: Birthday Paradoxon

Collision Resolution

for example by closed hashing

entries: elements $\rightsquigarrow$ sequences of elements



Hashing with Chaining

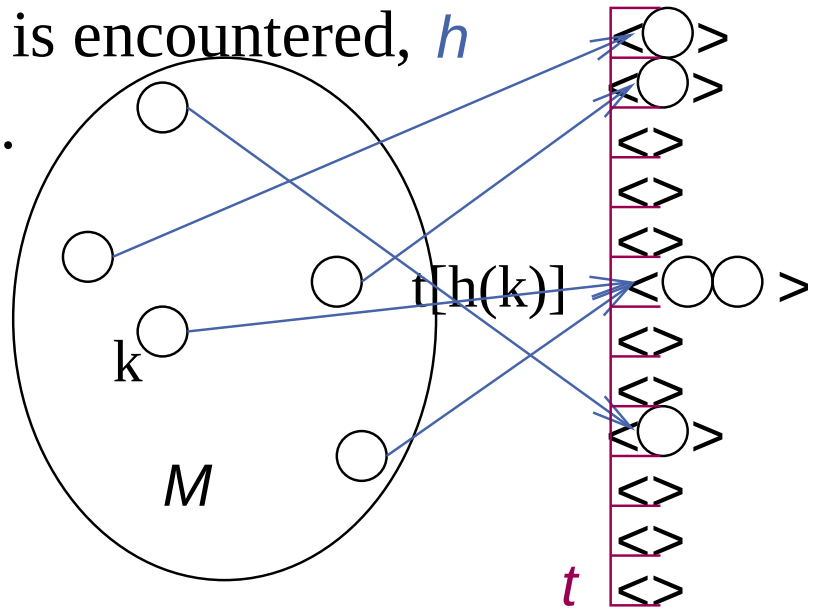
Implement sequences in closed hashing by singly linked lists

insert(e): Insert e at the beginning of $t[h(e)]$. constant time

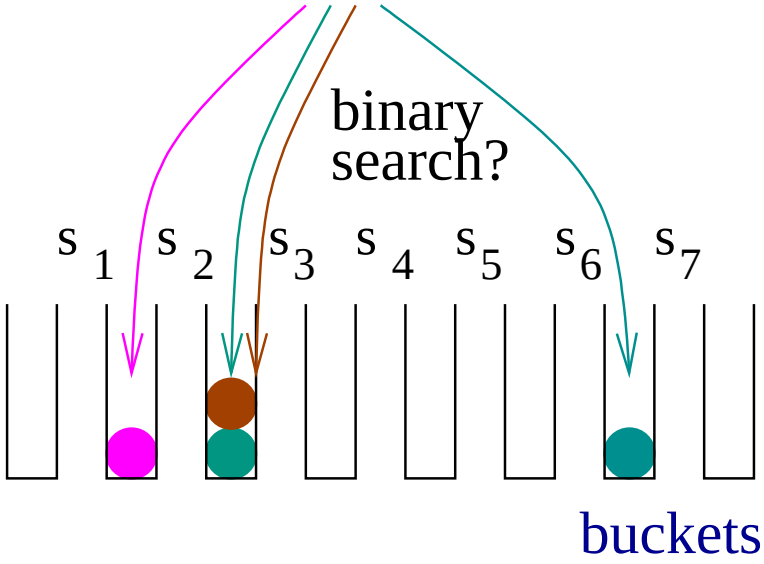
remove(k): Scan through $t[h(k)]$. If an element e with $h(e) = k$ is encountered, remove it and return.

find(k) : Scan through $t[h(k)]$.
If an element e with $h(e) = k$ is encountered, h return it. Otherwise, return $\perp$.

$\mathcal{O}(|M|)$ worst case time for remove and find



A Review of Probability



sample space Ω

events: subsets of Ω

p_x =probability of $x \in \Omega$

$\mathbb{P}[\mathscr{E}] = \sum_{x \in E} p_x$

random variable $X_0 : \Omega \to \mathbb{R}$

Example from hashing

random hash functions $\{0..m-1\}^{\text{Key}}$

$\mathscr{E}_{42} = \{h \in \Omega : h(4) = h(2)\}$

uniform distr. $p_h = m^{-|\text{Key}|}$

$\mathbb{P}[\mathscr{E}_{42}] = \frac{1}{m}$

$X = |\{e \in M : h(e) = 0\}|.$

expectation $\mathrm{E}[X_0] = \sum_{y \in \Omega} p_y X(y)$ $\mathrm{E}[X] = \frac{|M|}{m}$ (*)

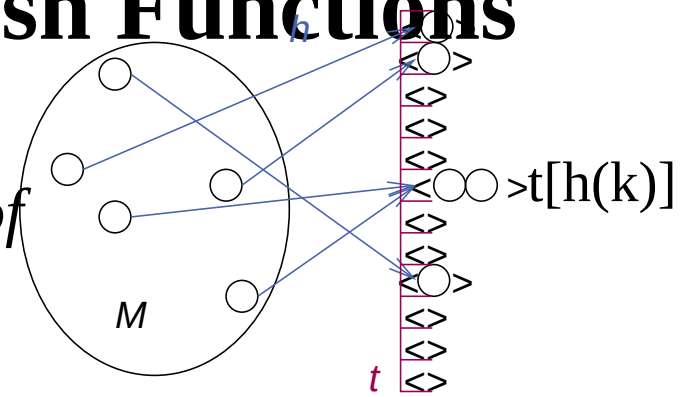
Linearity of Expectation: $\mathrm{E}[X+Y] = \mathrm{E}[X] + \mathrm{E}[Y]$

Proof of (*):

Consider the 0-1 RV $X_e = 1$ if $h(e) = 0$ for $e \in M$ and $X_e = 0$ else.

$$\mathrm{E}[X_0] = \mathrm{E}[\sum_{e \in M} X_e] = \sum_{e \in M} \mathrm{E}[X_e] = \sum_{e \in M} \mathbb{P}[X_e = 1] = |M| \cdot \frac{1}{m}$$

Analysis for Random Hash Functions



Satz 1. *The expected execution time of* remove(k) *and* find(k) *is* $\mathcal{O}(1)$ *if* $|M| = \mathcal{O}(m)$.

Beweis. Constant time plus the time for scanning $t[h(k)]$.

$X := |t[h(k)]| = |\{e \in M : h(e) = h(k)\}|$.

Consider the 0-1 RV $X_e = 1$ if $h(e) = h(k)$ for $e \in M$ and $X_e = 0$ else.

$$\mathrm{E}[X] = \mathrm{E}[\sum_{e \in M} X_e] = \sum_{e \in M} \mathrm{E}[X_e] = \sum_{e \in M} \mathbb{P}[X_e = 1] = \frac{|M|}{m}$$
$$= \mathcal{O}(1)$$

This is independent of the input set M. □

Universal Hashing

Idea: use only certain "easy" hash functions

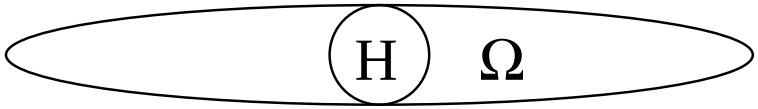
Definition:

$\mathcal{U} \subseteq \{0..m-1\}^{\text{Key}}$ is *universal*
if for all x, y in Key with $x \neq y$ and random $h \in \mathcal{U}$,

$$\mathbb{P}[h(x) = h(y)] = \frac{1}{m} \quad .$$

Satz 2. *Theorem 1 also applies to universal families of hash functions.*

Beweis. For $\Omega = \mathcal{U}$ we still have $\mathbb{P}[X_e = 1] = \frac{1}{m}$.
The rest is as before. □



H
Ω

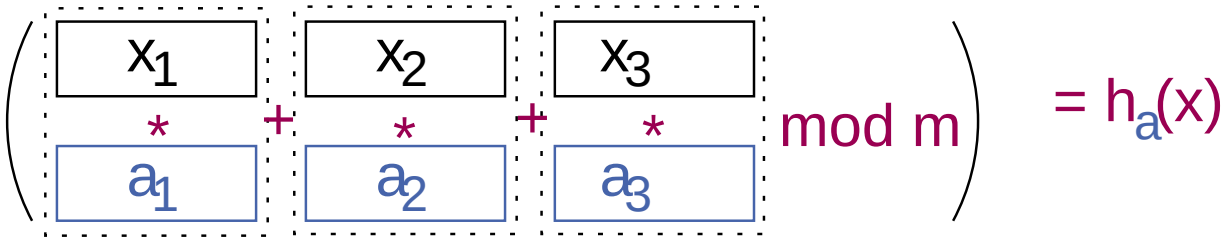
A Simple Universal Family

Assume m is prime, Key $\subseteq \{0,\ldots,m-1\}^k$

Satz 3. *For* $\mathbf{a} = (a_1,\ldots,a_k) \in \{0,\ldots,m-1\}^k$ *define*

$h_{\mathbf{a}}(\mathbf{x}) = \mathbf{a}\cdot\mathbf{x} \bmod m$, $H^{\cdot} = \left\{h_{\mathbf{a}} : \mathbf{a} \in \{0..m-1\}^k\right\}$.

$H^{\cdot}$ *is a universal family of hash functions*



Beweis. Consider $\mathbf{x} = (x_1, \ldots, x_k)$, $\mathbf{y} = (y_1, \ldots, y_k)$ with $x_j \neq y_j$
count **a**-s with $h_{\mathbf{a}}(\mathbf{x}) = h_{\mathbf{a}}(\mathbf{y})$.
For each choice of a_is, $i \neq j$, $\exists$ exactly one a_j with
$h_{\mathbf{a}}(\mathbf{x}) = h_{\mathbf{a}}(\mathbf{y})$:

$$\sum_{1 \leq i \leq k} a_i x_i \equiv \sum_{1 \leq i \leq k} a_i y_i \,(\mathbf{mod}\ m)$$

$$\Leftrightarrow a_j(x_j - y_j) \equiv \sum_{i \neq j, 1 \leq i \leq k} a_i(y_i - x_i) \,(\mathbf{mod}\ m)$$

$$\Leftrightarrow a_j \equiv (x_j - y_j)^{-1} \sum_{i \neq j, 1 \leq i \leq k} a_i(y_i - x_i) \,(\mathbf{mod}\ m)$$

m^{k-1} ways to choose the a_i with $i \neq j$.
m^k is total number of **a**s, i.e.,

$$\mathbb{P}\left[h_{\mathbf{a}}(x) = h_{\mathbf{a}}(\mathbf{y})\right] = \frac{m^{k-1}}{m^k} = \frac{1}{m}.$$

□

Bit Based Universal Families

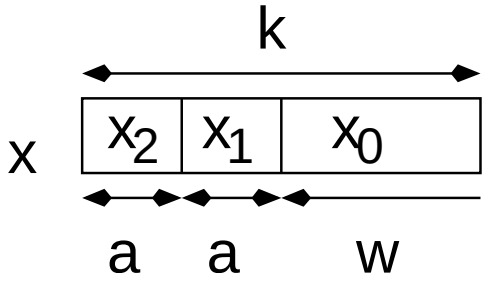
Let $m = 2^w$, $\mathsf{Key} = \{0,1\}^k$

Bit-Matrix Multiplication: $H^{\oplus} = \left\{ h_{\mathbf{M}} : \mathbf{M} \in \{0,1\}^{w \times k} \right\}$

where $h_{\mathbf{M}}(\mathbf{x}) = \mathbf{M}x$ (arithmetics $\bmod 2$, i.e., xor, and)

Table Lookup: $H^{\oplus[]} = \left\{ h^{\oplus[]}_{(t_1,\ldots,t_b)} : t_i \in \{0..m-1\}^{\{0..w-1\}} \right\}$

where $h^{\oplus[]}_{(t_1,\ldots,t_b)}((x_0,x_1,\ldots,x_b)) = x_0 \oplus \bigoplus_{i=1}^{b} t_i[x_i]$



Hashing with Linear Probing

Open hashing: go back to original idea.

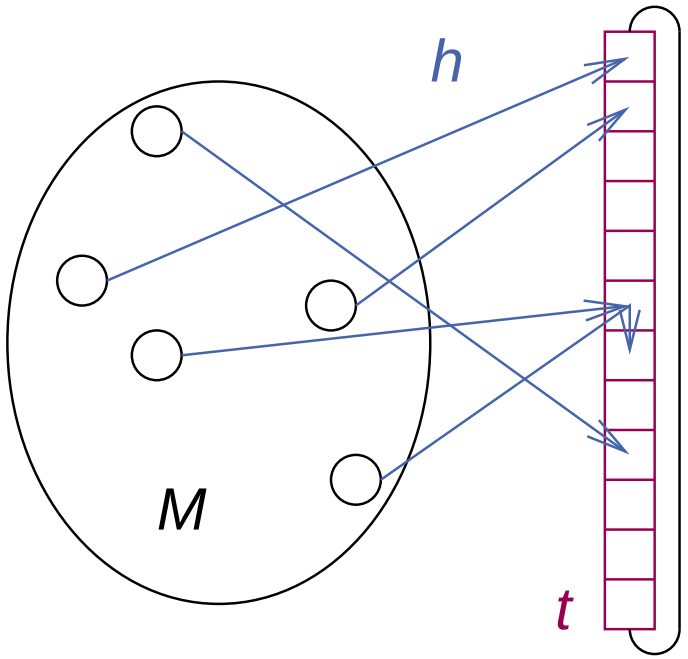
Elements are directly stored in the table.

Collisions are resolved by finding other entries.

linear probing: search for next free place by scanning the table.

Wrap around at the end.

- simple
- space efficient
- cache efficient



The Easy Part

Class BoundedLinearProbing$(m, m' : \mathbb{N}; h : \text{Key} \to 0..m-1)$

$t = [\bot, \ldots, \bot]$: **Array** $[0..m+m'-1]$ **of** Element

invariant $\forall i : t[i] \neq \bot \Rightarrow \forall j \in \{h(t[i])..i-1\} : t[i] \neq \bot$

Procedure insert$(e : \text{Element})$

for $i := h(e)$ **to** ∞ **while** $t[i] \neq \bot$ **do** ;

assert $i < m + m' - 1$

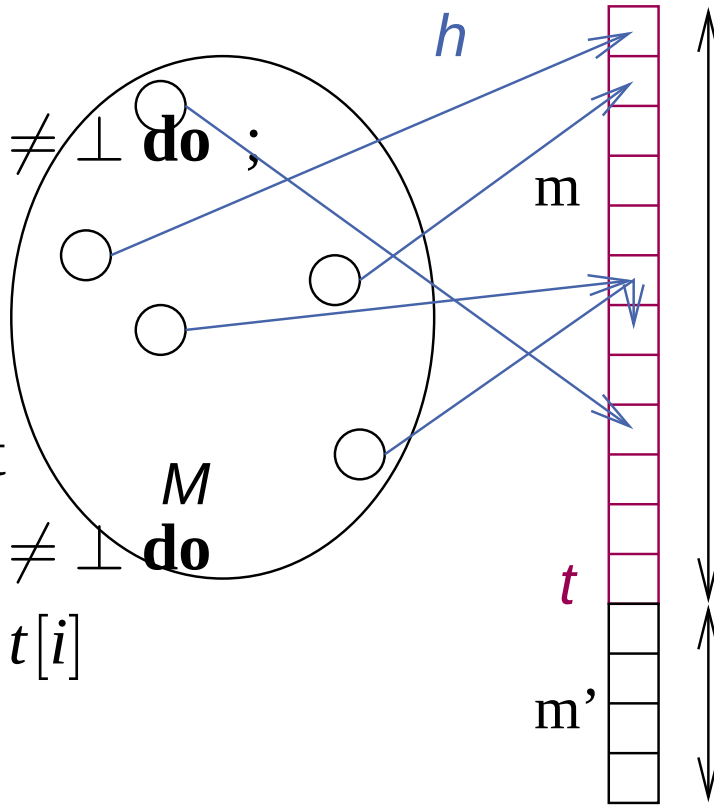
$t[i] := e$

Function find$(k : \text{Key}) : \text{Element}$

for $i := h(e)$ **to** ∞ **while** $t[i] \neq \bot$ **do**

if $t[i] = k$ **then return** $t[i]$

return $\bot$



Remove

example: $t = [\ldots, \underset{h(z)}{x}, y, z, \ldots]$, remove$(x)$

invariant $\forall i : t[i] \neq \bot \Rightarrow \forall j \in \{h(t[i])..i-1\} : t[i] \neq \bot$

Procedure remove$(k : \text{Key})$

```
for i := h(k) to ∞ while k ≠ t[i] do                    // search k
    if t[i] = ⊥ then return                              // nothing to do
//we plan for a hole at i.
for j := i+1 to ∞ while t[j] ≠ ⊥ do
    //Establish invariant for t[j].
    if h(t[j]) ≤ i then
        t[i] := t[j]                                     // Overwrite removed element
        i := j                                           // move planned hole
t[i] := ⊥                                                // erase freed entry
```

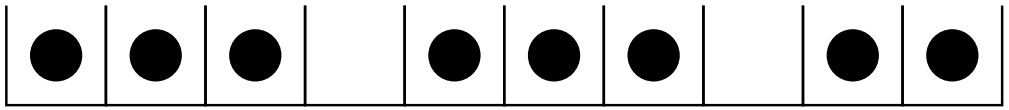
More Hashing Issues

- High probability and worst case guarantees
  $\rightsquigarrow$ more requirements on the hash functions
- Hashing as a means of load balancing in parallel systems, e.g., storage servers
  - Different disk sizes and speeds
  - Adding disks / replacing failed disks without much copying

Space Efficient Hashing with Worst Case Constant Access Time

Represent a set of n elements (with associated information) using space $(1+\varepsilon)n$.
Support operations insert, delete, lookup, (doall) efficiently.

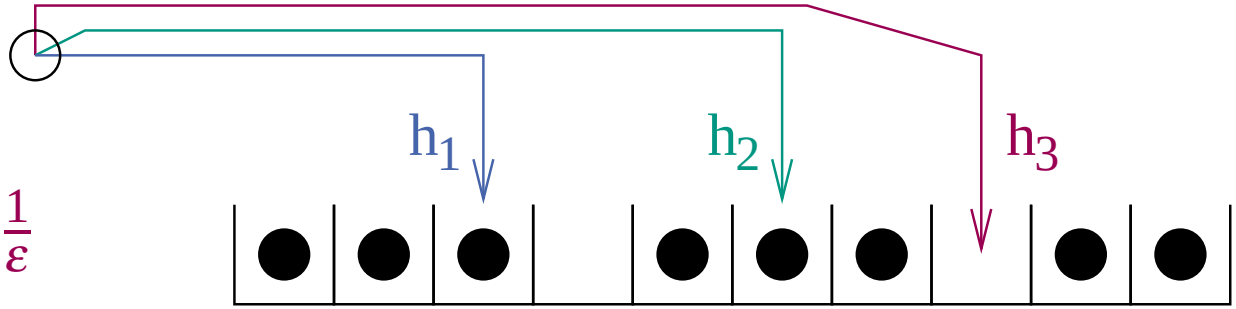
Assume a truly random hash function h



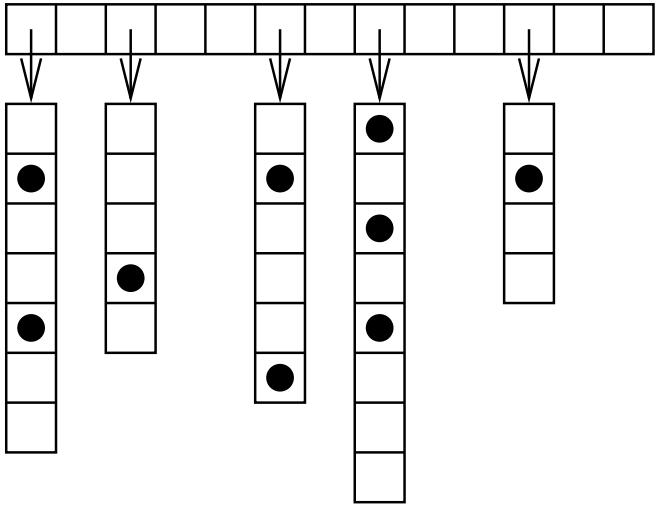
Related Work

Uniform hashing:

Expected time $\approx \frac{1}{\varepsilon}$



Dynamic Perfect Hashing,
[Dietzfelbinger et al. 94]
Worst case constant time
for lookup but ε is not small.



Approaching the Information Theoretic Lower Bound:
[Brodnik Munro 99,Raman Rao 02]
Space $(1+o(1))\times$lower bound without associated information
[Pagh 01] static case.

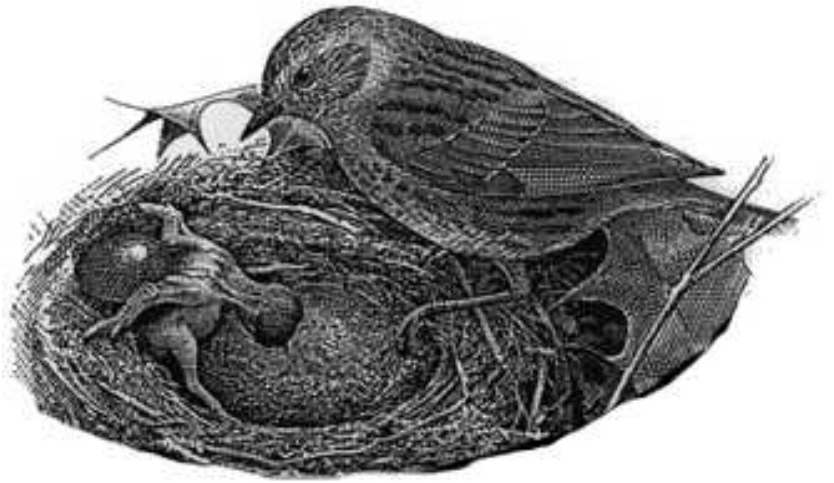
Cuckoo Hashing

[Pagh Rodler 01] Table of size 2

Two choices for each element.

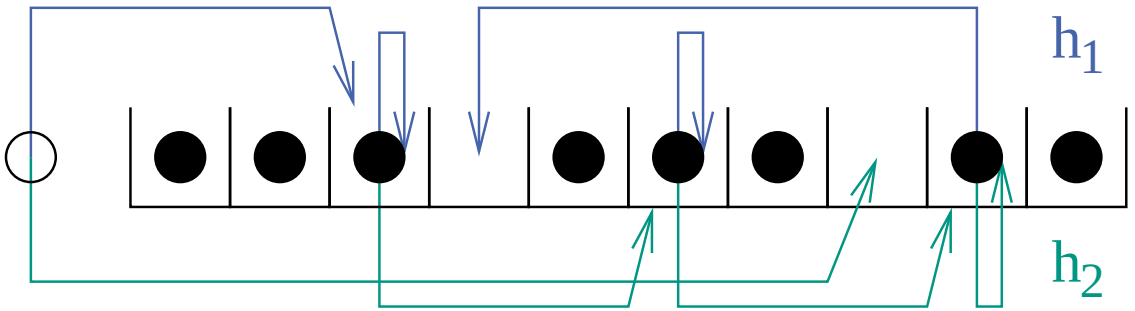
Insert moves elements;

rebuild if necessary.



Very fast lookup and insert.

Expected constant insertion time.

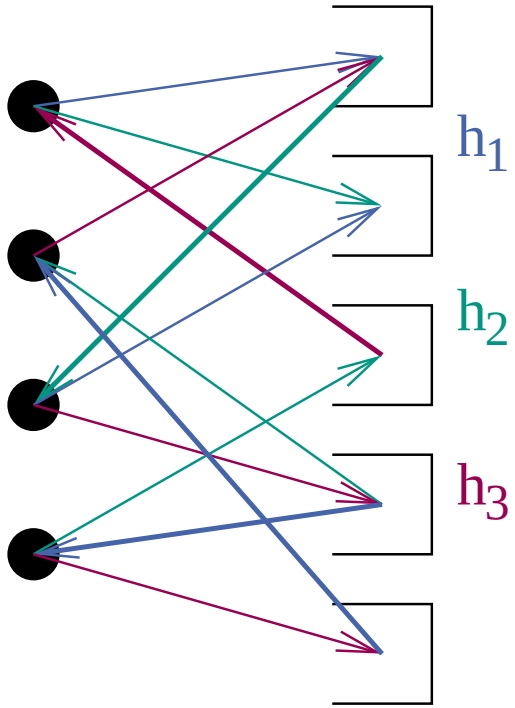


d-ary Cuckoo Hashing

d choices for each element.

Worst case d probes for delete and lookup.

Task: maintain perfect matching
in the bipartite graph
$(L = \text{Elements}, R = \text{Cells}, E = \text{Choices})$,
e.g., insert by BFS of random walk.

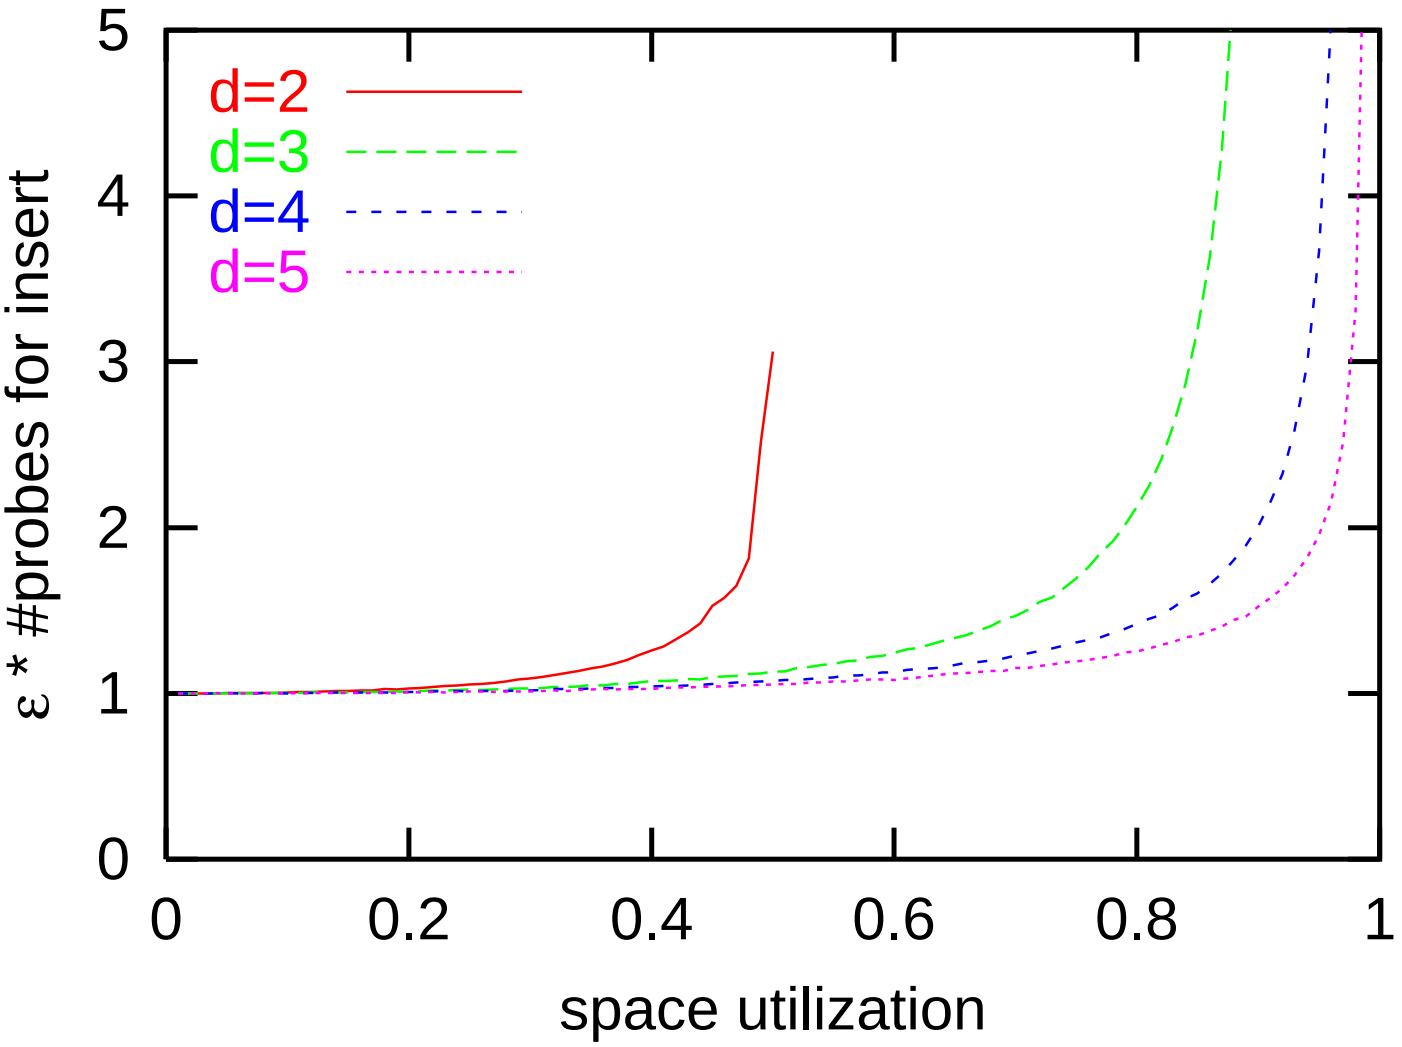


Tradeoff: Space $\leftrightarrow$ Lookup/Deletion Time

Lookup and Delete: $d = \mathcal{O}\left(\log \frac{1}{\varepsilon}\right)$ probes

Insert: $\left(\frac{1}{\varepsilon}\right)^{\mathcal{O}(\log(1/\varepsilon))}$, (experiments) $\longrightarrow \mathcal{O}(1/\varepsilon)$?

Experiments



Open Questions and Further Results

- Tight analysis of insertion
- Two choices with d slots each [Dietzfelbinger et al.]

  $\rightsquigarrow$ cache efficiency

Good Implementation?

- Automatic rehash
- Always correct

5 Minimum Spanning Trees

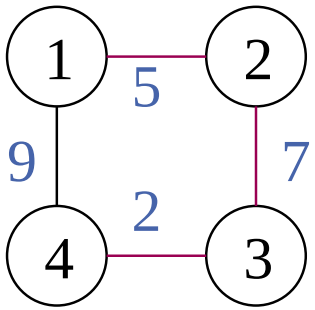
undirected Graph $G = (V, E)$.

nodes V, $n = |V|$, e.g., $V = \{1, \ldots, n\}$

edges $e \in E$, $m = |E|$, two-element subsets of V.

edge weight $c(e)$, $c(e) \in \mathbb{R}_+$.

G is connected, i.e., $\exists$ path between any two nodes.



Find a tree (V, T) with minimum weight $\sum_{e \in T} c(e)$ that connects all nodes.

MST: Overview

- Basics: Edge property and cycle property
- Jarník-Prim Algorithm
- Kruskals Algorithm
- Filter-Kruskal
- Comparison
- (Advanced algorithms using the cycle property)
- External MST

Applications

- Clustering
- Subroutine in combinatorial optimization, e.g., Held-Karp lower bound for TSP.
  Challenging real world instances???
- Image segementation $\longrightarrow$ [Diss. Jan Wassenberg]

Anyway: almost ideal “fruit fly” problem

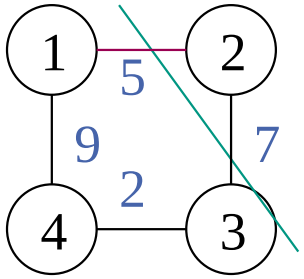
Selecting and Discarding MST Edges

The Cut Property

For any $S \subset V$ consider the cut edges

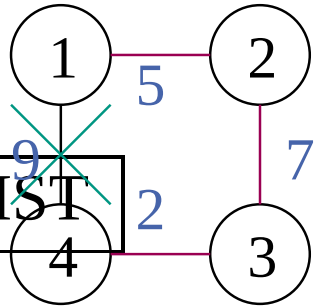
$C = \{\{u,v\} \in E : u \in S, v \in V \setminus S\}$

The lightest edge in C can be used in an MST.



The Cycle Property

The heaviest edge on a cycle is not needed for an MST



The Jarník-Prim Algorithm [Jarník 1930, Prim 1957]

Idea: grow a tree

$T := \emptyset$

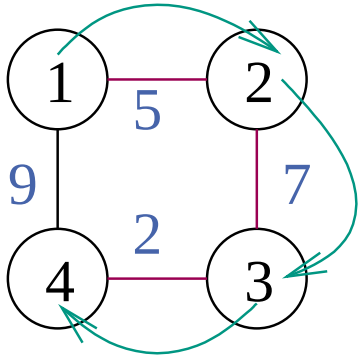
$S := \{s\}$ for arbitrary start node s

repeat $n-1$ times

find (u,v) fulfilling the cut property for S

$S := S \cup \{v\}$

$T := T \cup \{(u,v)\}$



Implementation Using Priority Queues

Function jpMST(V, E, w) : Set **of** Edge

dist$=[\infty,\ldots,\infty]$: **Array** $[1..n]$// dist$[v]$ is distance of v from the tree

pred : **Array of** Edge// pred$[v]$ is shortest edge between S and v

q : PriorityQueue **of** Node with dist$[\cdot]$ as priority

dist$[s]$:= 0; q.insert(s) for any $s \in V$

for $i := 1$ **to** $n-1$ **do do**

u := q.deleteMin() // new node for S

dist$[u]$:= 0

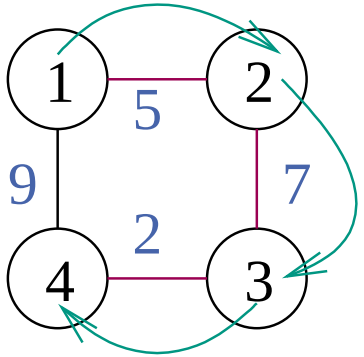
foreach $(u,v) \in E$ **do**

if $c((u,v)) <$ dist$[v]$ **then**

dist$[v]$:= $c((u,v))$; pred$[v]$:= (u,v)

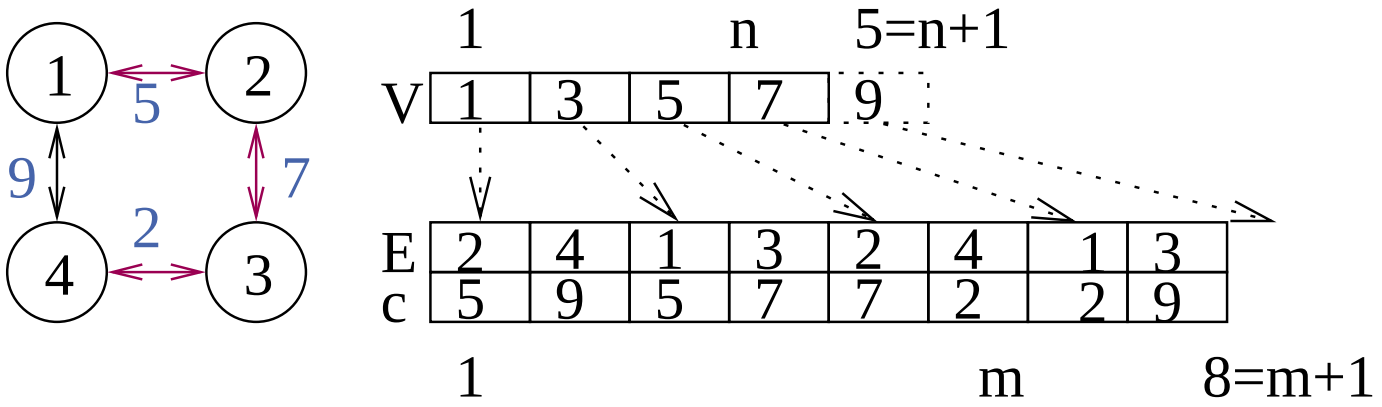
if $v \in q$ **then** q.decreaseKey(v) **else** q.insert(v)

return $\{\text{pred}[v] : v \in V \setminus \{s\}\}$



Graph Representation for Jarník-Prim

We need node → incident edges



+ fast (cache efficient)
+ more compact than linked lists
– difficult to change
– Edges are stored twice

Analysis

- $\mathcal{O}(m+n)$ time outside priority queue
- n deleteMin (time $\mathcal{O}(n \log n)$)
- $\mathcal{O}(m)$ decreaseKey (time $\mathcal{O}(1)$ amortized)

$\rightsquigarrow$ $\mathcal{O}(m+n\log n)$ using Fibonacci Heaps

practical implementation using simpler pairing heaps.

But analysis is still partly open!

Kruskal's Algorithm [1956]

$T := \emptyset$ // subforest of the MST

foreach $(u,v) \in E$ in ascending order of weight **do**

  if u and v are in different subtrees of T **then**

    $T := T \cup \{(u,v)\}$ // Join two subtrees

return T

The Union-Find Data Structure

Class UnionFind($n : \mathbb{N}$) // Maintain a partition of $1..n$

parent$=[n+1,\ldots,n+1]$: **Array** $[1..n]$ **of** $1..n+\lceil \log n \rceil$

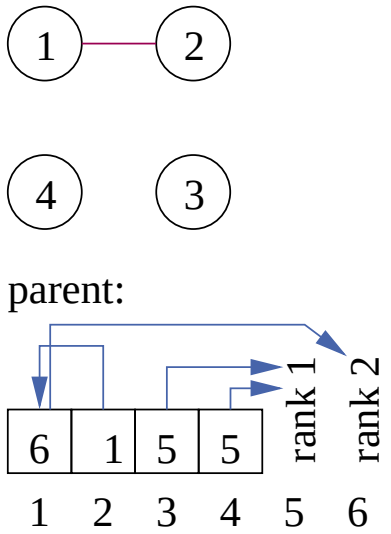
Function find($i : 1..n$) : $1..n$

if parent$[i] > n$ **then return** i

else $i' :=$ find(parent$[i]$)

parent$[i] := i'$

return i'



Procedure link($i, j : 1..n$)

assert i and j are leaders of different subsets

if parent$[i] <$ parent$[j]$ **then** parent$[i] := j$

else if parent$[i] >$ parent$[j]$ **then** parent$[j] := i$

else parent$[j] := i$; parent$[i]$++ // next generation

Procedure union(i, j) **if** find(i) $\neq$ find(j) **then** link(find(i), find(j))

Kruskal Using Union Find

T : UnionFind(n)

sort E in ascending order of weight

kruskal(E)

Procedure kruskal(E)

    foreach $(u,v) \in E$ **do**

        $u' := T$.find(u)

        $v' := T$.find(v)

        if $u' \neq v'$ **then**

            output (u,v)

            T.link(u',v')

Graph Representation for Kruskal

Just an edge sequence (array) !

- $+$ very fast (cache efficient)
- $+$ Edges are stored only once
- $\rightsquigarrow$ more compact than adjacency array

Analysis

$\mathcal{O}(\text{sort}(m) + m\alpha(m,n)) = \mathcal{O}(m \log m)$ where α is the inverse Ackermann function

Kruskal versus Jarník-Prim I

- Kruskal wins for very sparse graphs
- Prim seems to win for denser graphs
- Switching point is unclear
  - How is the input represented?
  - How many decreaseKeys are performed by JP?
    (average case: $n \log \frac{m}{n}$ [Noshita 85])
  - Experimental studies are quite old [Moret Shapiro 91],
    use slow graph representation for both algs,
    and artificial inputs

see attached slides.

5.1 Filtering by Sampling Rather Than Sorting

R:= random sample of r edges from E
F :=MST(R) // Wlog assume that F spans V
L:= $\emptyset$ // "light edges" with respect to R
foreach $e \in E$ **do** // Filter
    C := the unique cycle in $\{e\} \cup F$
    if e is not heaviest in C **then**
        L:= $L \cup \{e\}$
return MST$((L \cup F))$

5.1.1 Analysis

[Chan 98, KKK 95]

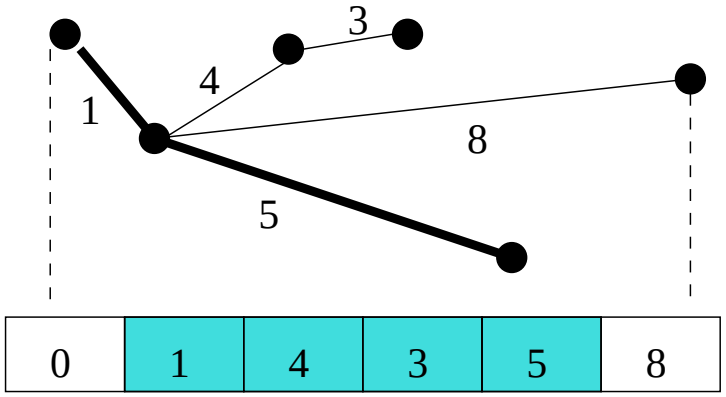
Observation: $e \in L$ only if $e \in \text{MST}(R \cup \{e\})$.

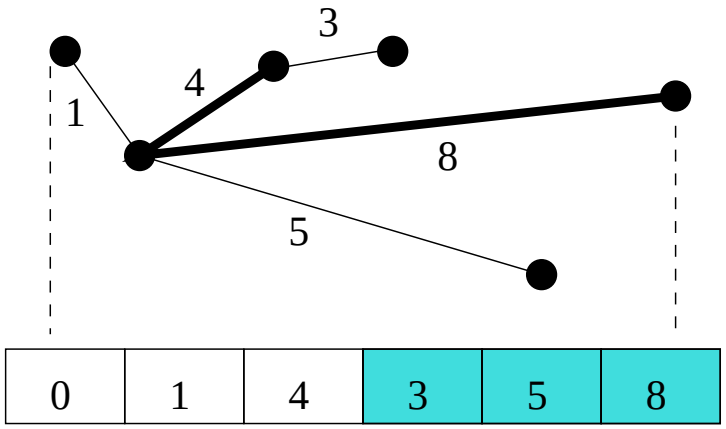
(Otherwise e could replace some heavier edge in F).

Lemma 4. $\text{E}[|L \cup F|] \leq \frac{mn}{r}$

MST Verification by Interval Maxima

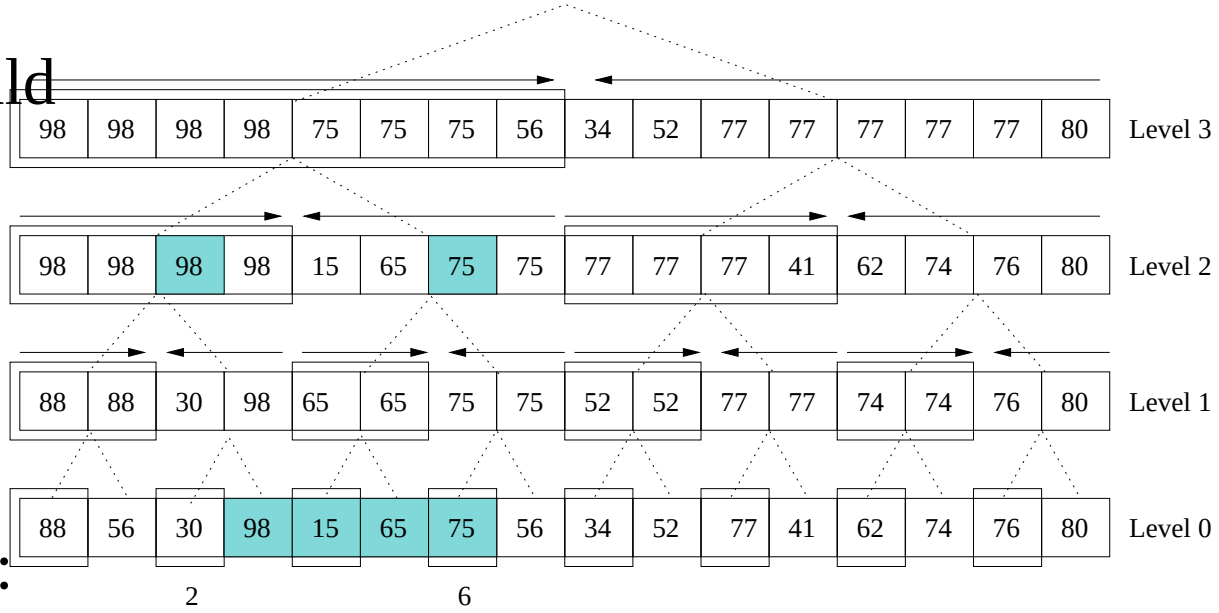
- Number the nodes by the order they were added to the MST by Prim's algorithm.
- w_i = weight of the edge that inserted node i.
- Largest weight on path$(u,v) = \max\{w_j \| u < j \leq v\}$.





Interval Maxima

Preprocessing: build $n \log n$ size array PreSuf.



To find $\max a[i..j]$:

- Find the level of the LCA: $\ell = \lfloor \log_2(i \oplus j) \rfloor$.
- Return $\max(\text{PreSuf}[\ell][i], \text{PreSuf}[\ell][j])$.
- Example: $2 \oplus 6 = 010 \oplus 110 = 100 \Rightarrow \ell = 2$

A Simple Filter Based Algorithm

Choose $r = \sqrt{mn}$.

We get expected time

$$T_{\text{Prim}}(\sqrt{mn}) + \mathcal{O}(n \log n + m) + T_{\text{Prim}}(\tfrac{mn}{\sqrt{mn}}) = \mathcal{O}(n \log n + m)$$

The constant factor in front of the m is very small.

Vector Machine
"worst case"

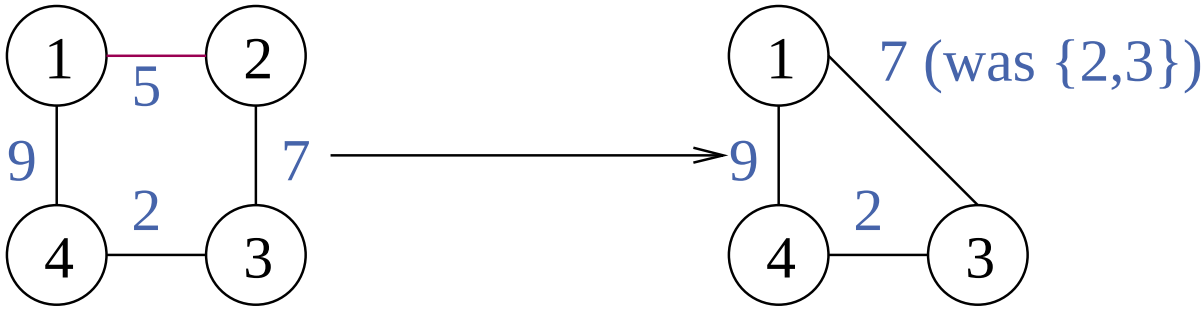
Edge Contraction

Let $\{u,v\}$ denote an MST edge.

Eliminate v:

forall $(w,v) \in E$ **do**

$E := E \setminus (w,v) \cup \{(w,u)\}$ // but remember orignal terminals

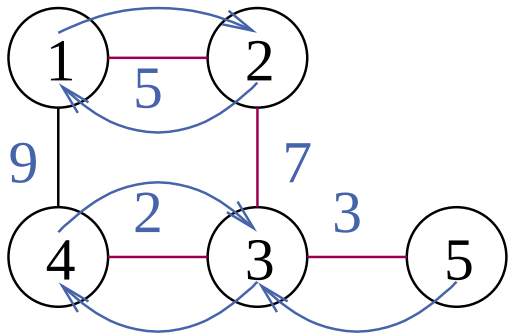


Boruvka's Node Reduction Algorithm

For each node find the lightest incident edge.
Include them into the MST (cut property)
contract these edges,

Time $\mathcal{O}(m)$

At least halves the number of remaining nodes



5.2 Simpler and Faster Node Reduction

for $i := n$ **downto** $n' + 1$ **do**

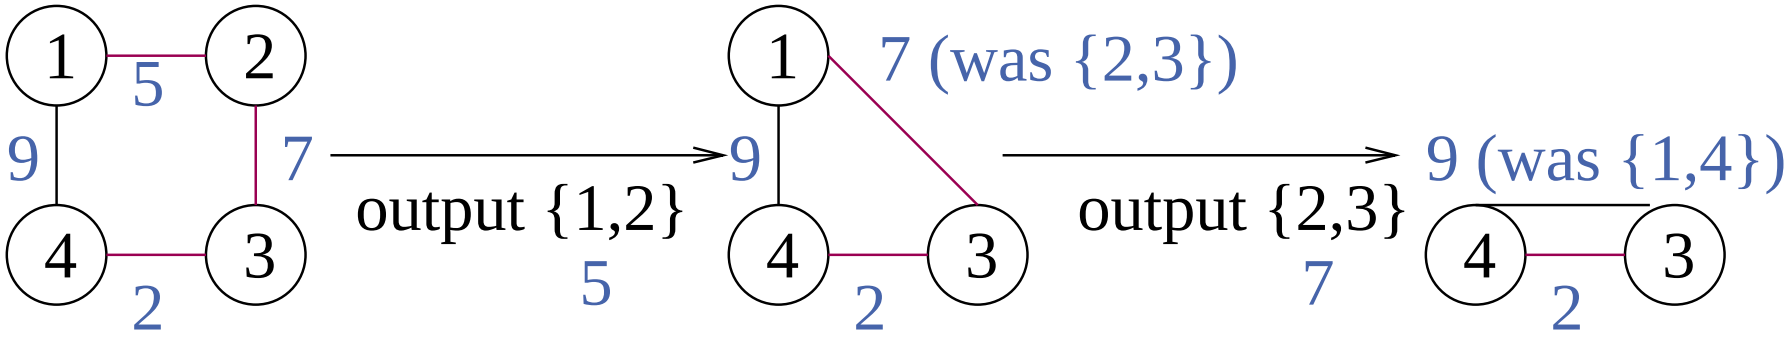
pick a random node v

find the lightest edge (u, v) out of v and output it

contract (u, v)

$$\mathrm{E}[\mathrm{degree}(v)] \leq 2m/i$$

$$\sum_{n' < i \leq n} \frac{2m}{i} = 2m \left(\sum_{0 < i \leq n} \frac{1}{i} - \sum_{0 < i \leq n'} \frac{1}{i} \right) \approx 2m(\ln n - \ln n') = 2m \ln \frac{n}{n'}$$



5.3 Randomized Linear Time Algorithm

1. Factor 8 node reduction (3× Boruvka or sweep algorithm) $\mathcal{O}(m+n)$.
2. $R \Leftarrow m/2$ random edges. $\mathcal{O}(m+n)$.
3. $F \Leftarrow MST(R)$ [Recursively].
4. Find light edges L (edge reduction). $\mathcal{O}(m+n)$ $\mathrm{E}[|L|] \leq \frac{mn/8}{m/2} = n/4$.
5. $T \Leftarrow MST(L \cup F)$ [Recursively].

$T(n,m) \leq T(n/8, m/2) + T(n/8, n/4) + c(n+m)$

$T(n,m) \leq 2c(n+m)$ fulfills this recurrence.

5.4 External MSTs

Semiexternal Algorithms

Assume $n \leq M - 2B$:

run Kruskal's algorithm using external sorting

Streaming MSTs

If M is yet a bit larger we can even do it with m/B I/Os:

$T := \emptyset$ // current approximation of MST

while there are any unprocessed edges **do**

load any $\Theta(M)$ unprocessed edges E'

$T := \mathsf{MST}(T \cup E')$ // for any internal MST alg.

Corollary: we can do it with linear expected internal work

Disadvantages to Kruskal:

Slower in practice

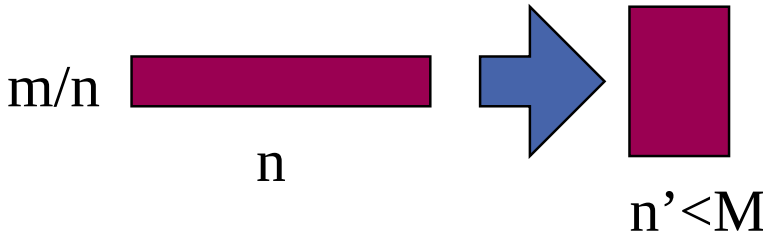
Smaller max. n

General External MST

while $n > M - 2B$ **do**

perform some node reduction

use semi-external Kruskal



Theory: $\mathcal{O}(\text{sort}(m))$ expected I/Os by externalizing the linear time algorithm.

(i.e., node reduction + edge reduction)

External Implementation I: Sweeping

π : random permutation $V \to V$

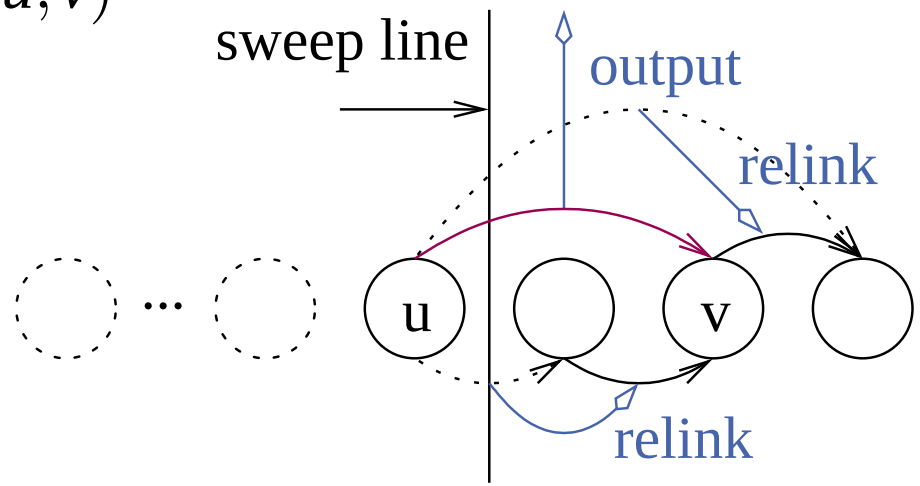
sort edges (u,v) by $\min(\pi(u),\pi(v))$

for $i := n$ **downto** $n' + 1$ **do**

pick the node v with $\pi(v) = i$

find the lightest edge (u,v) out of v and output it

contract (u,v)



Problem: how to implement relinking?

Relinking Using Priority Queues

Q: priority queue // Order: max node, then min edge weight

foreach $(\{u,v\},c) \in E$ **do** Q.insert($(\{\pi(u),\pi(v)\},c,\{u,v\})$)

current := $n+1$

loop

$(\{u,v\},c,\{u_0,v_0\})$:= Q.deleteMin()

if current$\neq \max\{u,v\}$**then**

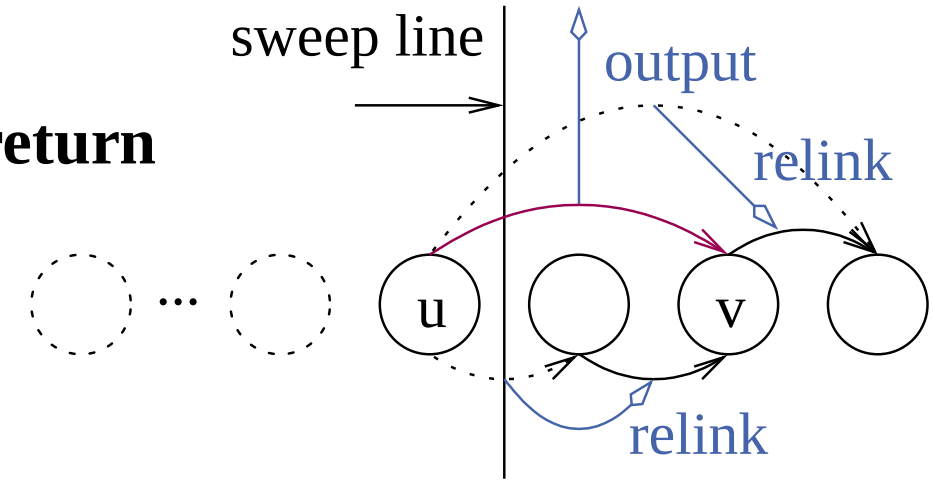
if current$= M+1$ **then return**

output $\{u_0,v_0\},c$

current := $\max\{u,v\}$

connect := $\min\{u,v\}$

else Q.insert($(\{\min\{u,v\},\text{connect}\},c,\{u_0,v_0\})$)

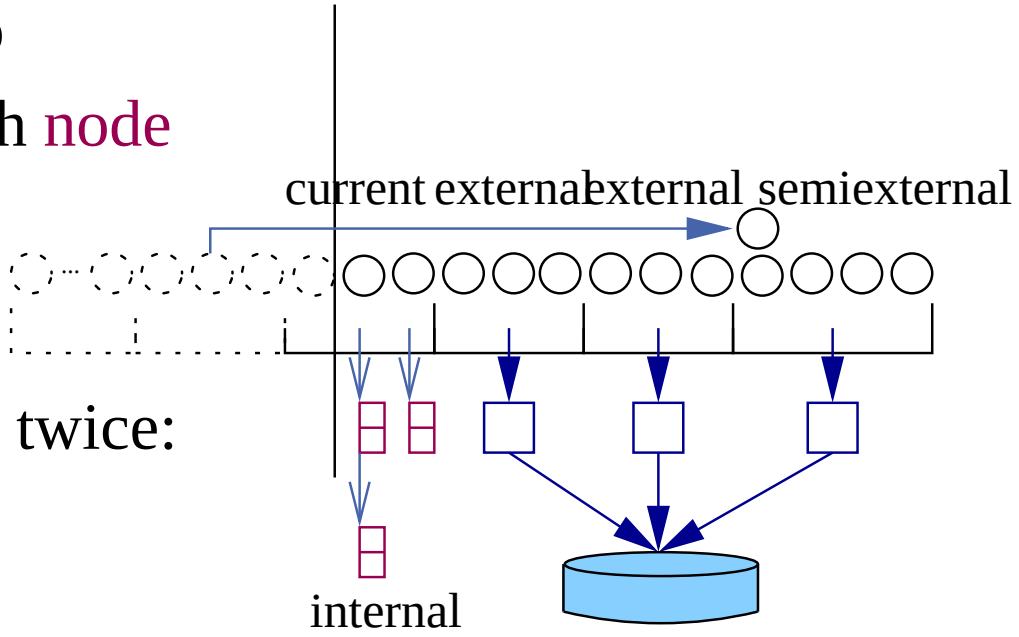


$\approx \text{sort}(10m \ln \frac{n}{M})$ I/Os with opt. priority queues [Sanders 00]

Problem: Compute bound

Sweeping with linear internal work

- Assume $m = \mathcal{O}\left(M^2/B\right)$
- $k = \Theta(M/B)$ external buckets with n/k nodes each
- M nodes for last "semiexternal" bucket
- split current bucket into internal buckets for each node



Sweeping:

Scan current internal bucket twice:

1. Find minimum
2. Relink

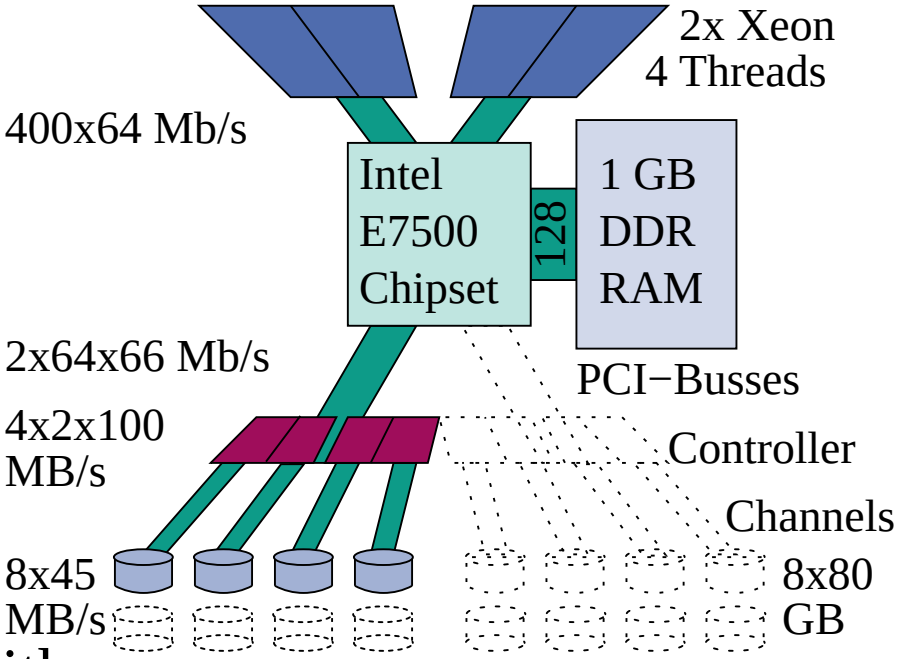
New external bucket: scan and put in internal buckets

Large degree nodes: move to semiexternal bucket

Experiments

Instances from “classical” MST study [Moret Shapiro 1994]

- sparse random graphs
- random geometric graphs
- grids
  $\mathcal{O}(\text{sort}(m))$ I/Os
  for planar graphs by
  removing parallel edges!



Other instances are rather dense or designed to fool specific algorithms.

MST Summary

- Edge reduction helps for very dense, “hard” graphs
- A fast and simple node reduction algorithm
  $\rightsquigarrow 4\times$ less I/Os than previous algorithms
- Refined semiexternal MST, use as base case
- Simple pseudo random permutations (no I/Os)
- A fast implementation
- Experiments with huge graphs (up to $n = 4 \cdot 10^9$ nodes)

External MST is feasible

Open Problems

- New experiments for (improved) Kruskal versus Jarník-Prim
- Realistic (huge) inputs
- Parallel external algorithms
- Implementations for other graph problems

Conclusions

- Even fundamental, “simple” algorithmic problems still raise interesting questions
- Implementation and experiments are important and were neglected by parts of the algorithms community
- Theory an (at least) equally important, essential component of the algorithm design process

More Algorithm Engineering on Graphs

- Count triangles in very large graphs. Interesting as a measure of clusteredness. (Cooperation with AG Wagner)
- External BFS (Master thesis Deepak Ajwani)
- Maximum flows: Is the theoretical best algorithm any good? (Jein)
- Approximate max. weighted matching (Studienarbeit Jens Maue)

Maximal Flows

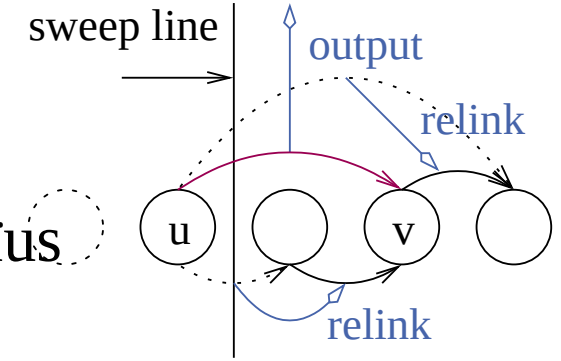
Theory: $\mathcal{O}\left(m\Lambda \log(n^2/m) \log U\right)$ binary blocking flow-algorithm mit $\Lambda = \min\{m^{1/2}, n^{2/3}\}$ [Goldberg-Rao-97].

Problem: best case $\approx$ worst case

[Hagerup Sanders Träff WAE 98]:

- Implementable generalization
- best case $\ll$ worst case
- best algorithms for some “difficult” instances

Ergebnis

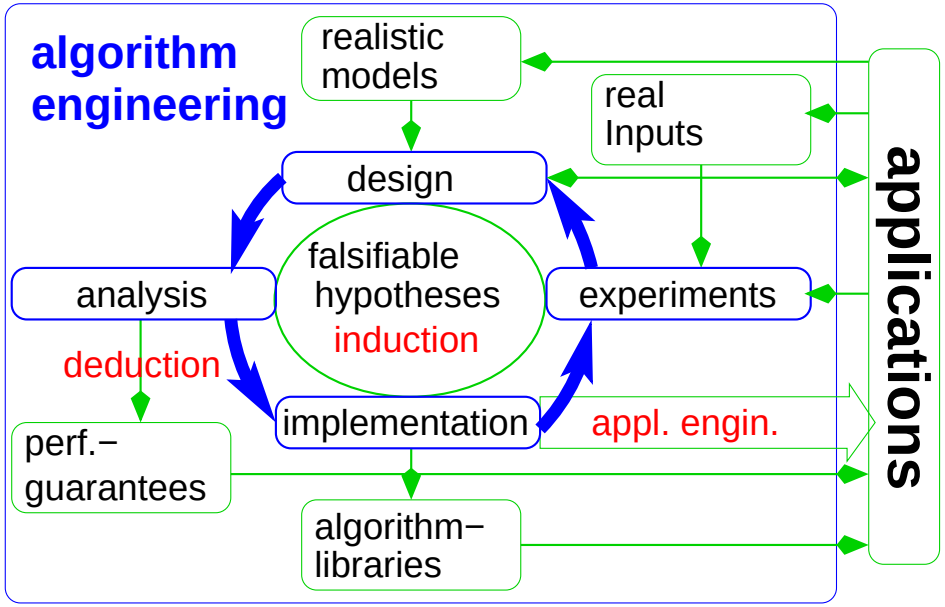


- Einfach extern implementierbar
- $n' = M \rightsquigarrow$ semiexterner Kruskal Algorithmus
- Insgesamt $\mathcal{O}\left(\text{sort}\left(m \ln \frac{n}{m}\right)\right)$ erwartete I/Os
- Für realistische Eingaben mindestens $4\times$ bisher als bisher bekannte Algorithmen
- Implementierung in `<stxxl>` mit bis zu 96 GByte gro/3en Graphen läuft „über Nacht“

More On Experimental Methodology

Scientific Method:

- Experiment need a possible outcome that falsifies a hypothesis
- Reproducible
  - keep data/code for at least 10 years
  - clear and detailed description in papers / TRs
  - share instances and code



Quality Criteris

- Beat the state of the art, globally – (not your own toy codes or the toy codes used in your community!)
- Clearly demonstrate this !
  - both codes use same data ideally from accepted benchmarks (not just your favorite data!)
  - comparable machines or fair (conservative) scaling
  - Avoid uncomparabilities like: “Yeah we are worse but but twice as fast”
  - real world data wherever possible
  - as much different inputs as possible
  - its fine if you are better just on some (important) inputs

Not Here but Important

- describing the setup
- finding sources of measurement errors
- reducing measurement errors (averaging, median,unloaded machine. . .)
- measurements in the creative phase of experimental algorithmics.

The Starting Point

- (Several) Algorithm(s)
- A few quantities to be measured: time, space, solution quality, comparisons, cache faults,... There may also be measurement errors.
- An unlimited number of potential inputs. $\rightsquigarrow$ condense to a few characteristic ones (size, $|V|$, $|E|$, ... or problem instances from applications)

Usually there is not a lack but an abundance of data $\neq$ many other sciences

The Process

Waterfall model?

1. Design
2. Measurement
3. Interpretation

Perhaps the paper should at least look like that.

The Process

- Eventually stop asking questions (Advisors/Referees listen !)
- build measurement tools
- automate (re)measurements
- Choice of Experiments driven by risk and opportunity
- Distinguish mode

  explorative: many different parameter settings, interactive, short turnaround times

  consolidating: many large instances, standardized measurement conditions, batch mode, many machines

Of Risks and Opportunities

Example: Hypothesis = my algorithm is the best

big risk: untried main competitor

small risk: tuning of a subroutine that takes 20 % of the time.

big opportunity: use algorithm for a new application

$\rightsquigarrow$ new input instances

Presenting Data from Experiments in Algorithmics

Restrictions

- black and white $\rightsquigarrow$ easy and cheap printing
- 2D (stay tuned)
- no animation
- no realism desired

Basic Principles

- Minimize nondata ink
  (form follows function, not a beauty contest,. . .)
- Letter size $\approx$ surrounding text
- Avoid clutter and overwhelming complexity
- Avoid boredom (too little data per m^2).
- Make the conclusions evident

Tables

- \+ easy
- − easy $\rightsquigarrow$ overuse
- \+ accurate values ($\neq$ 3D)
- \+ more compact than bar chart
- \+ good for unrelated instances (e.g. solution quality)
- − boring
- − no visual processing

rule of thumb that “tables usually outperform a graph for small data sets of 20 numbers or less” [Tufte 83]

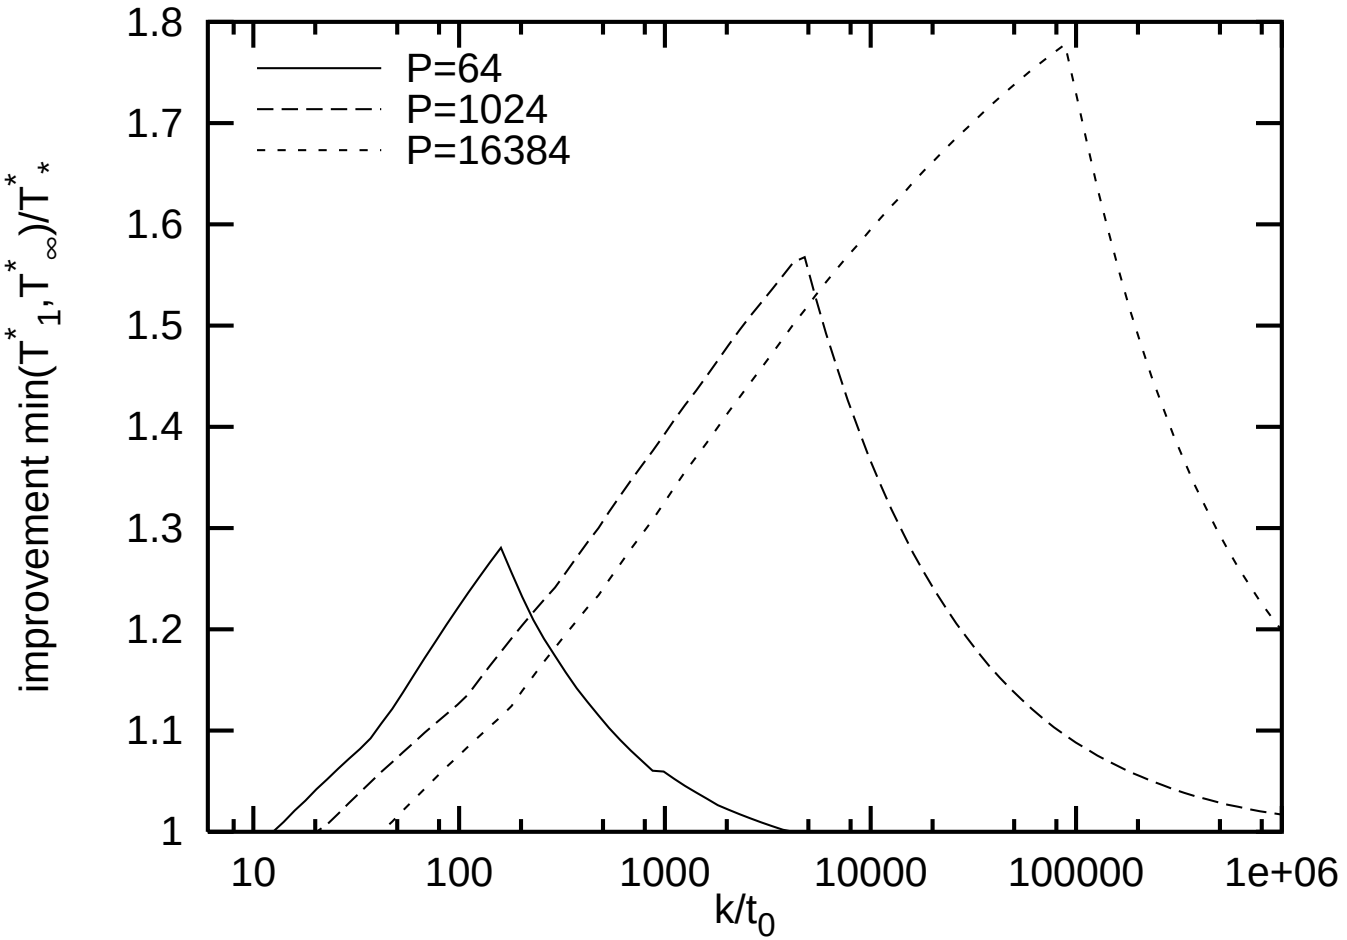
Curves in main paper, tables in appendix?

2D Figures

default: $x =$ input size, $y = f($execution time$)$

x Axis

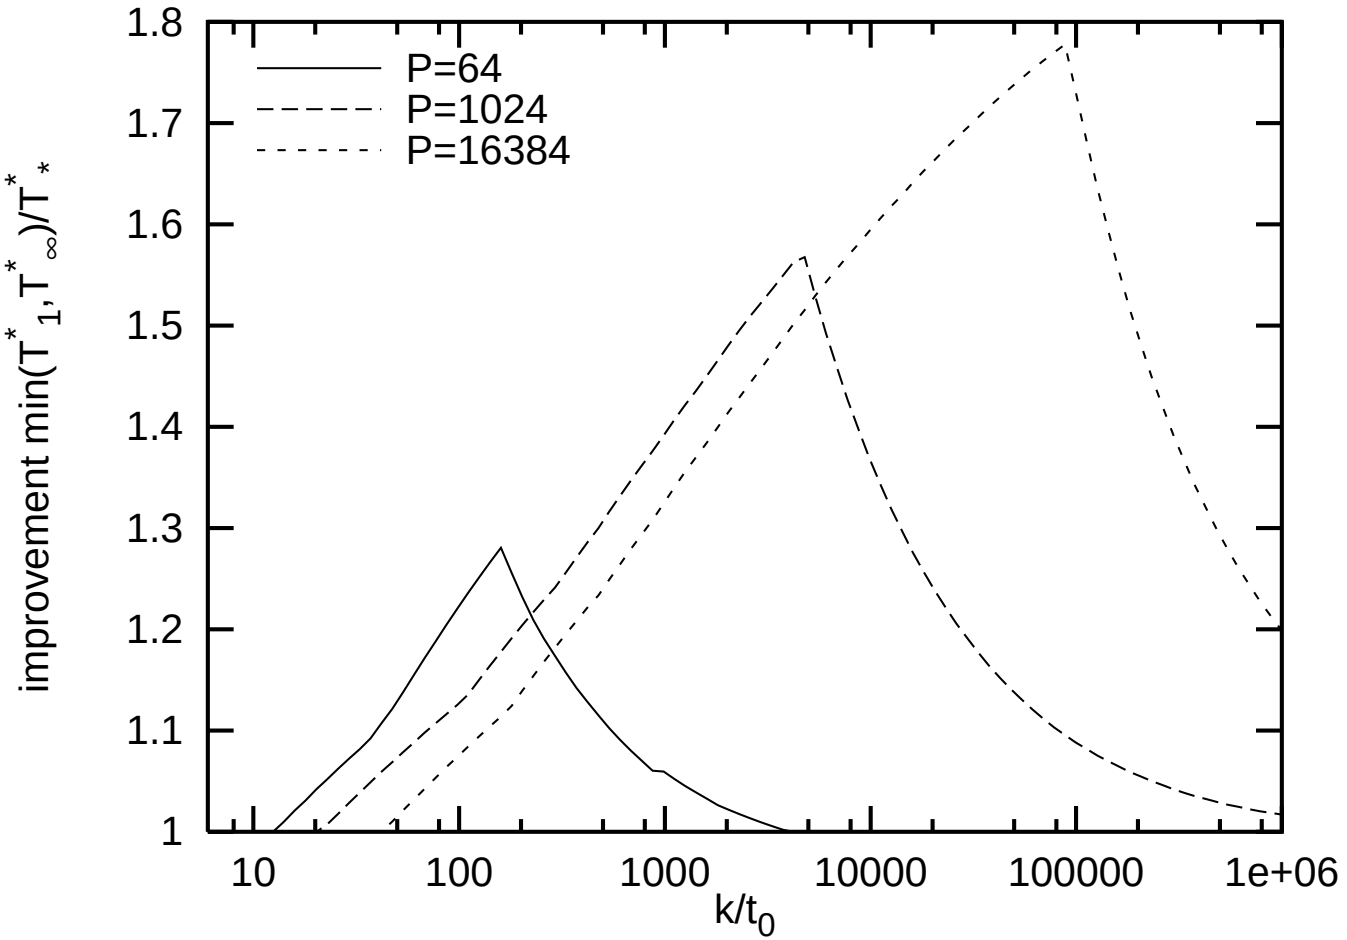
Choose unit to eliminate a parameter?



length k fractional tree broadcasting. latency $t_0 + k$

x Axis

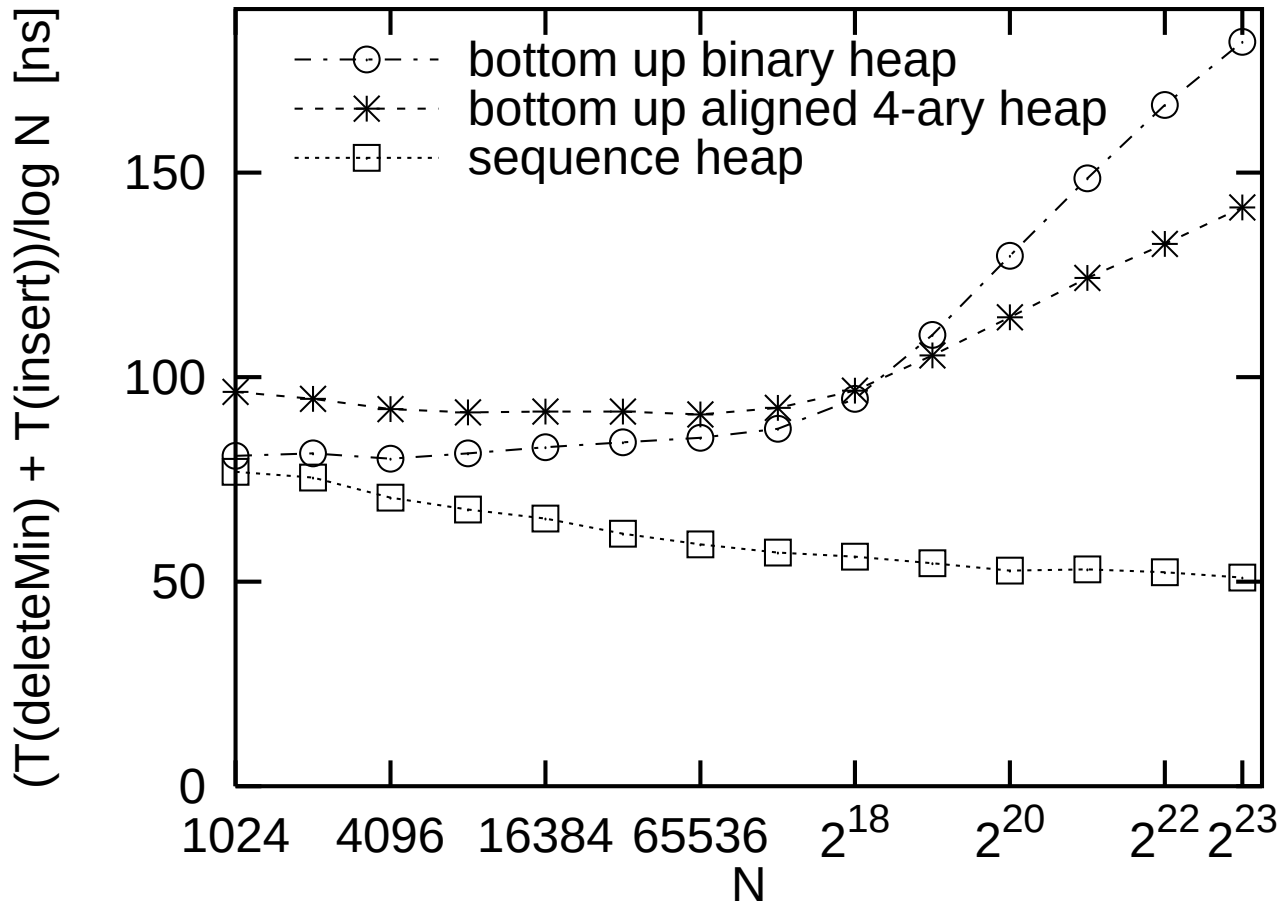
logarithmic scale?



yes if *x* range is wide

x Axis

logarithmic scale, powers of two (or $\sqrt{2}$)



with tic marks, (plus a few small ones)

gnuplot

```
set xlabel "N"
set ylabel "(time per operation)/log N  [ns]"
set xtics (256, 1024, 4096, 16384, 65536, "2^{18}" 262144,

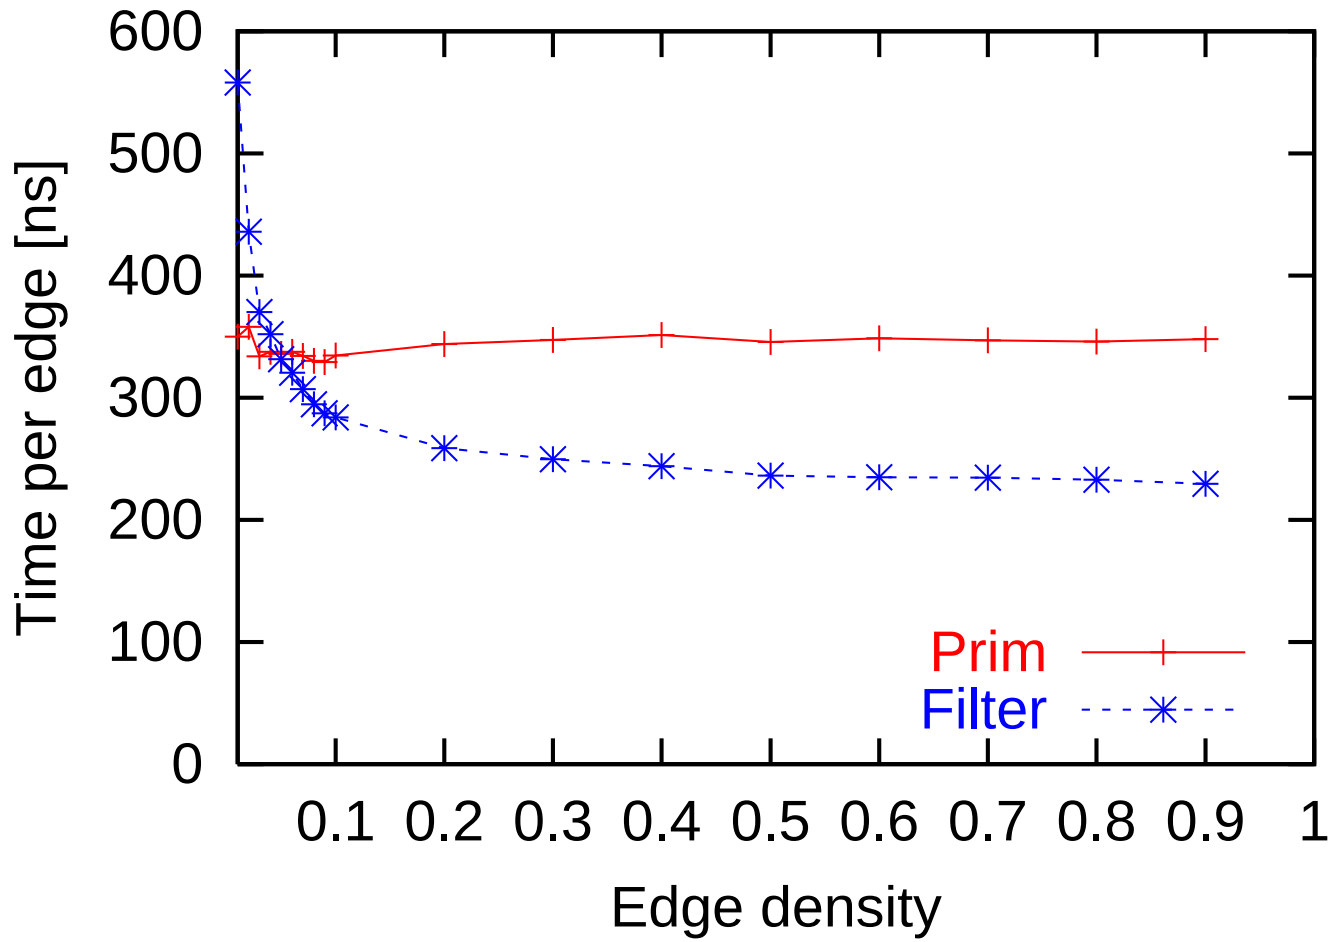
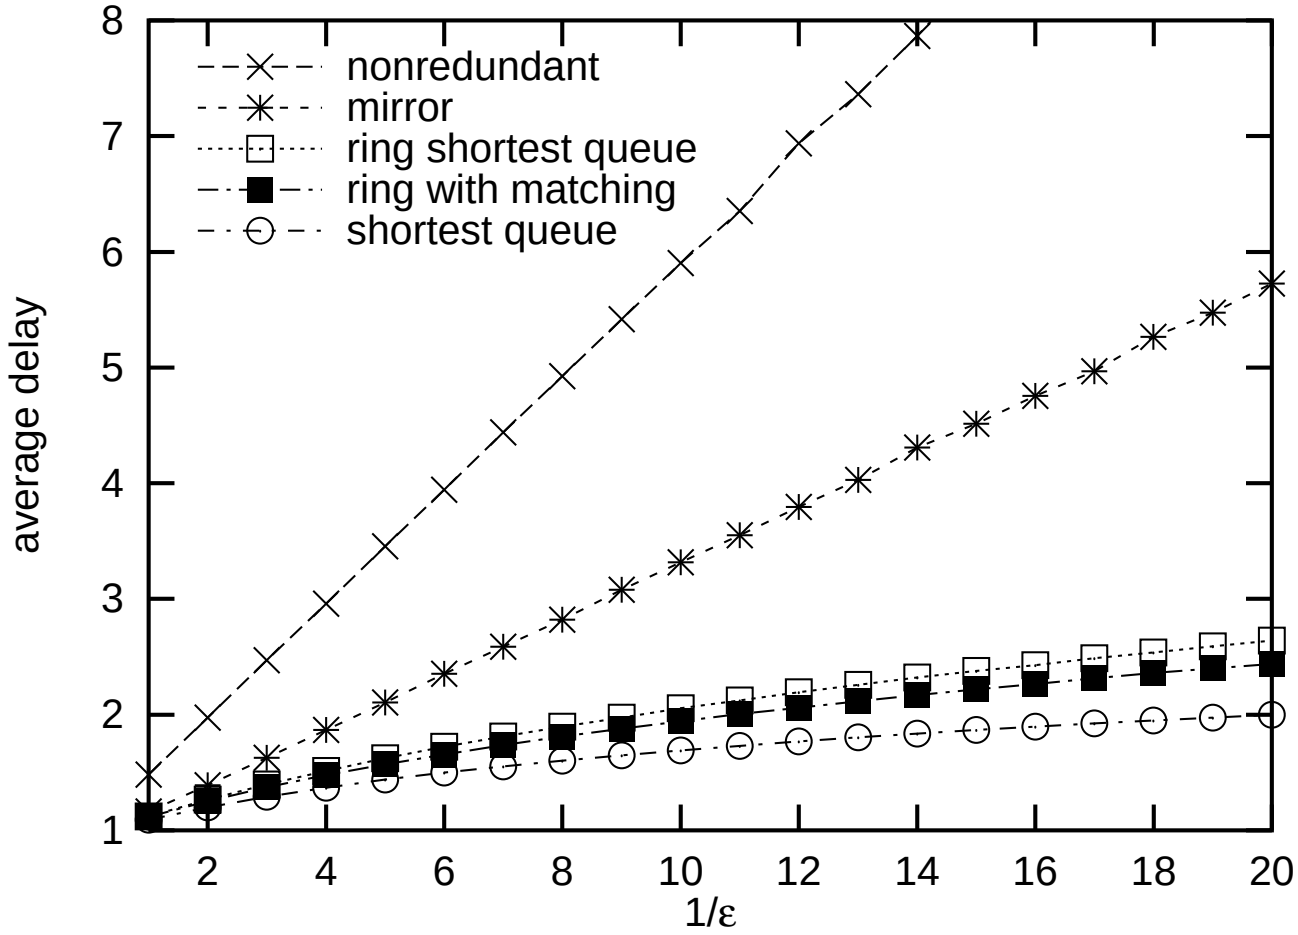
x Axis

linear scale for ratios or small ranges (#processor,...)



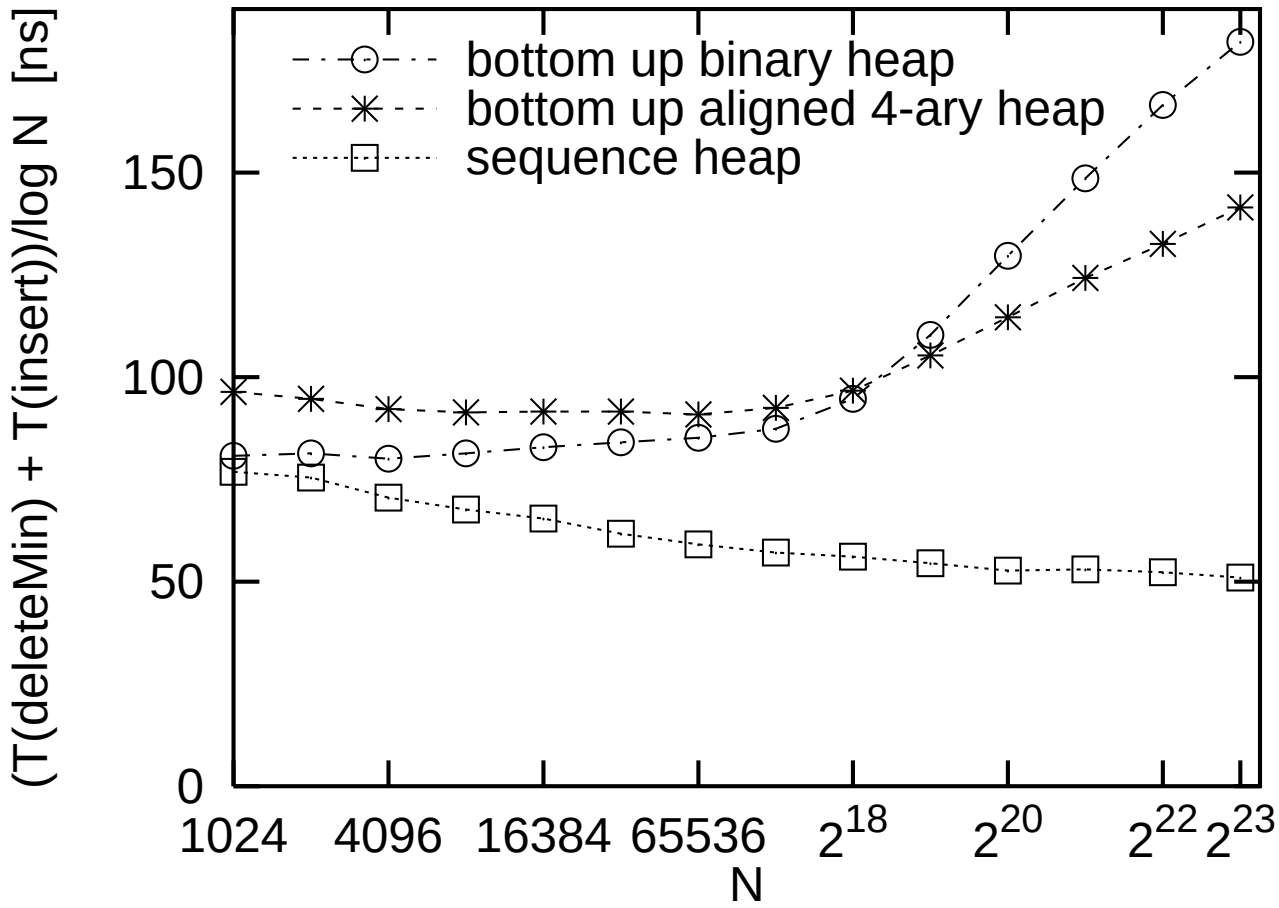
x Axis

An exotic scale: arrival rate $1 - \varepsilon$ of saturation point



y Axis

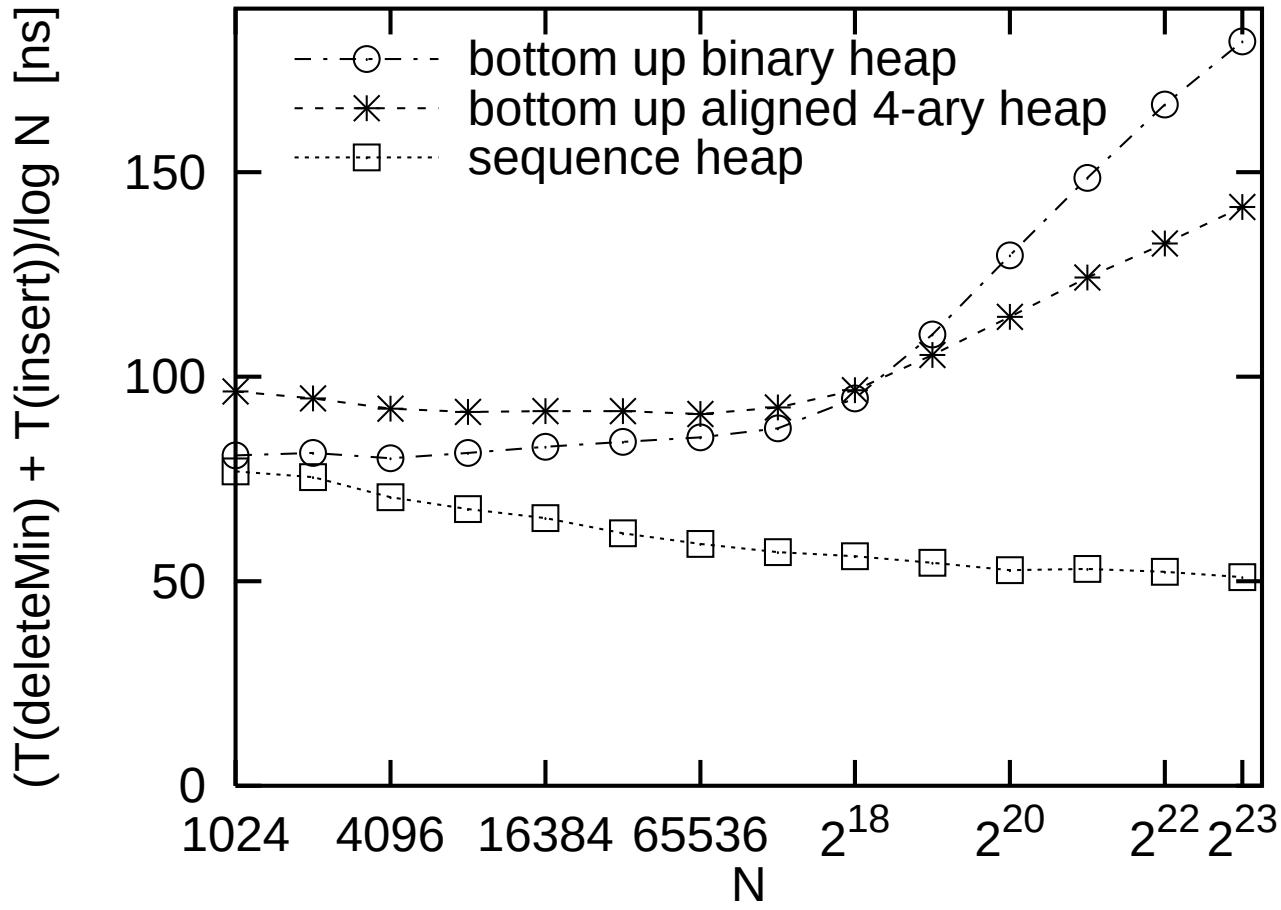
Avoid log scale ! scale such that theory gives ≈ horizontal lines



but give easy interpretation of the scaling function

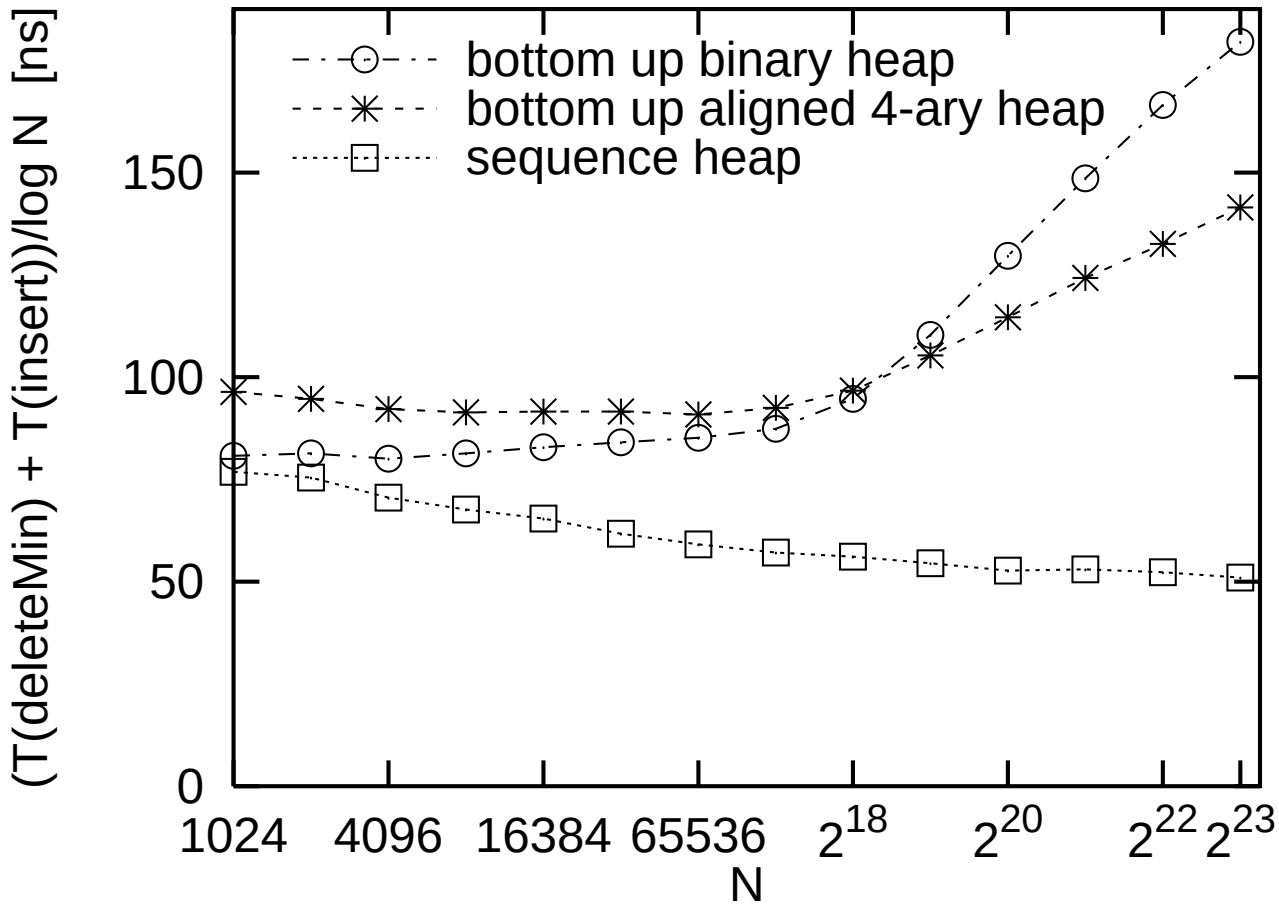
y Axis

give units



y Axis

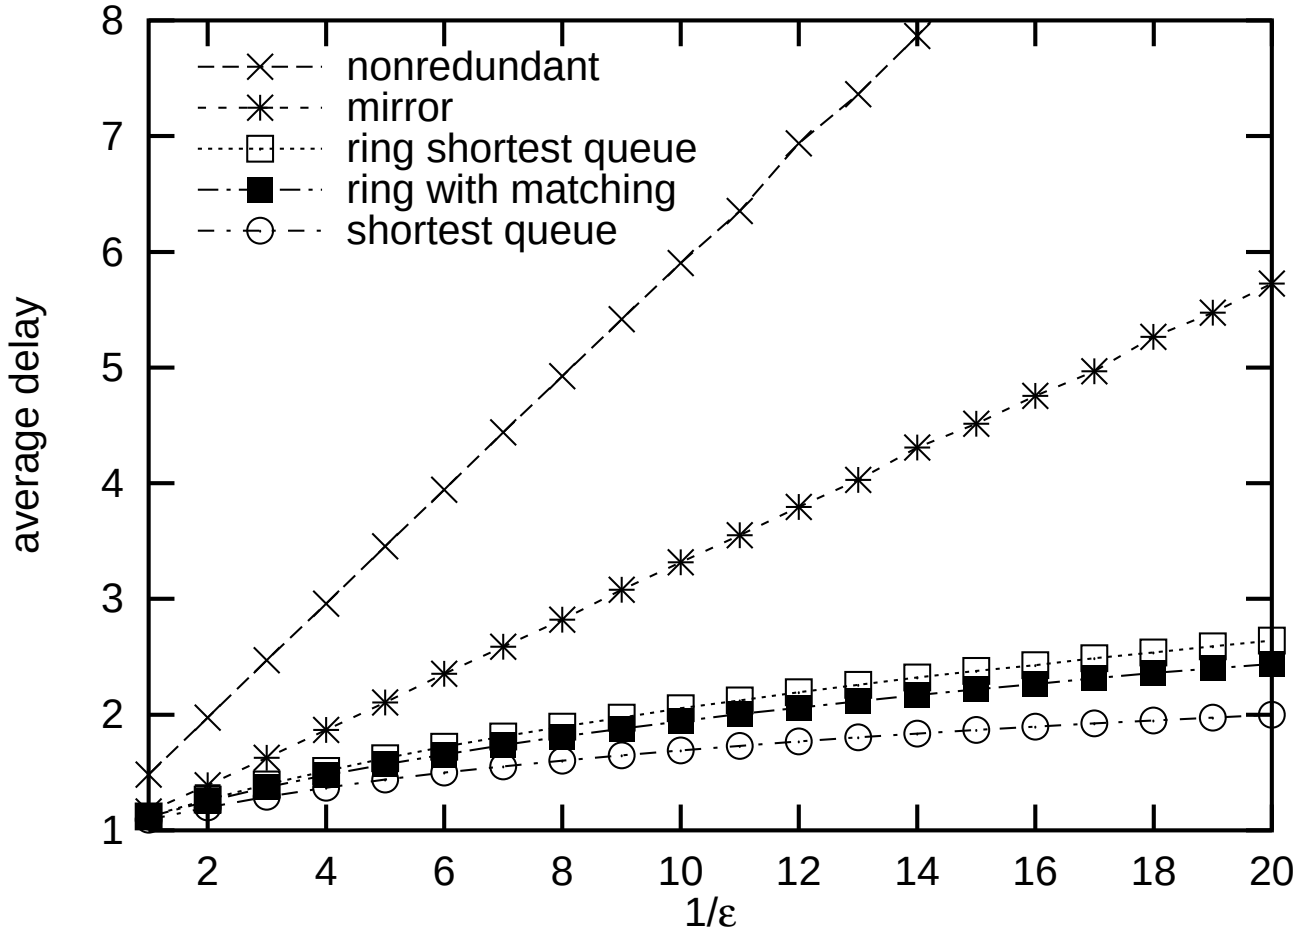
start from 0 if this does not waste too much space



you may assume readers to be out of Kindergarten

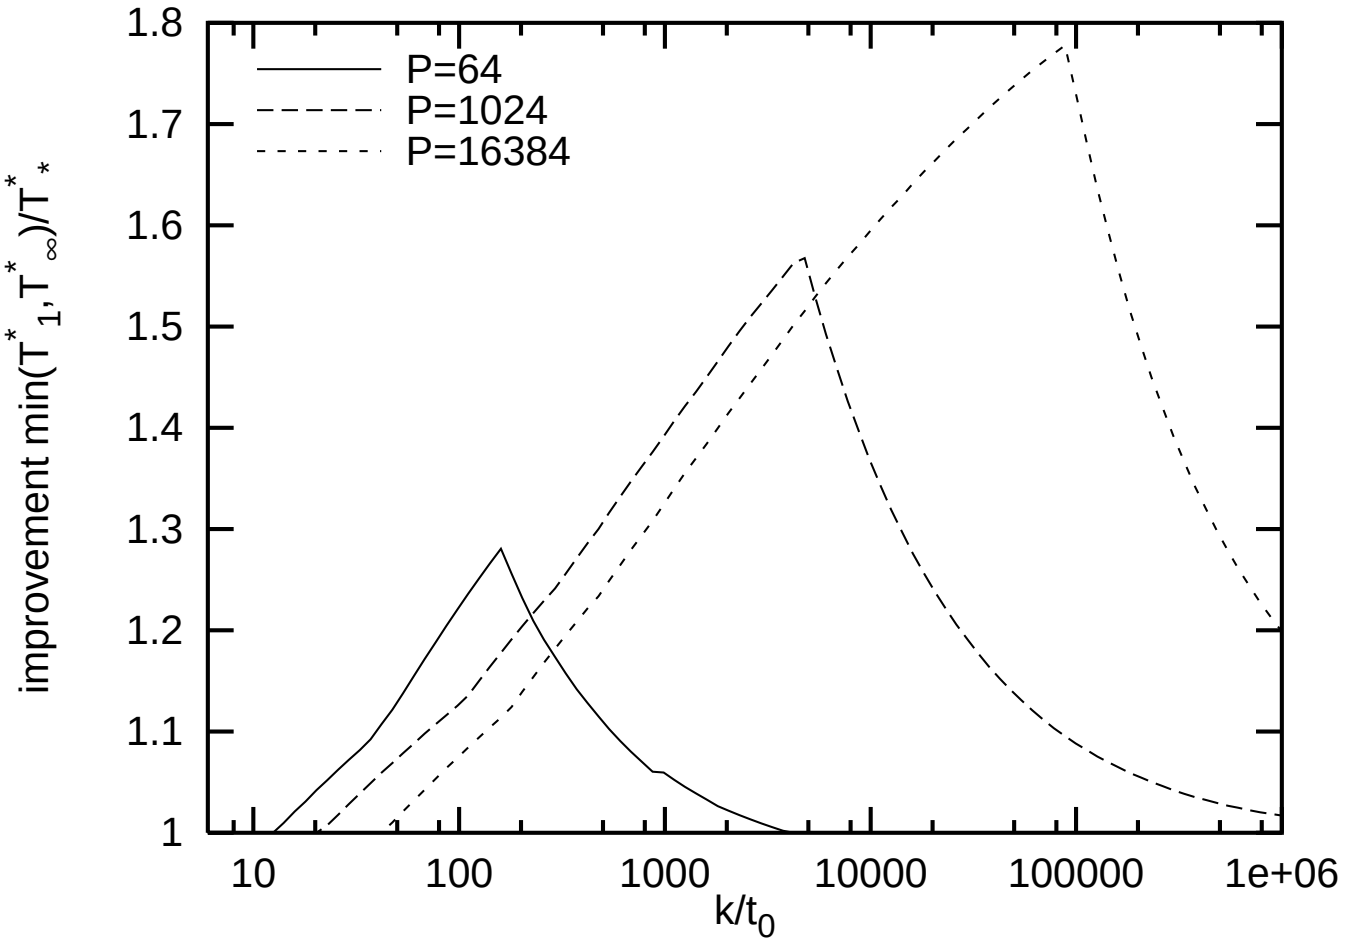
y Axis

clip outclassed algorithms



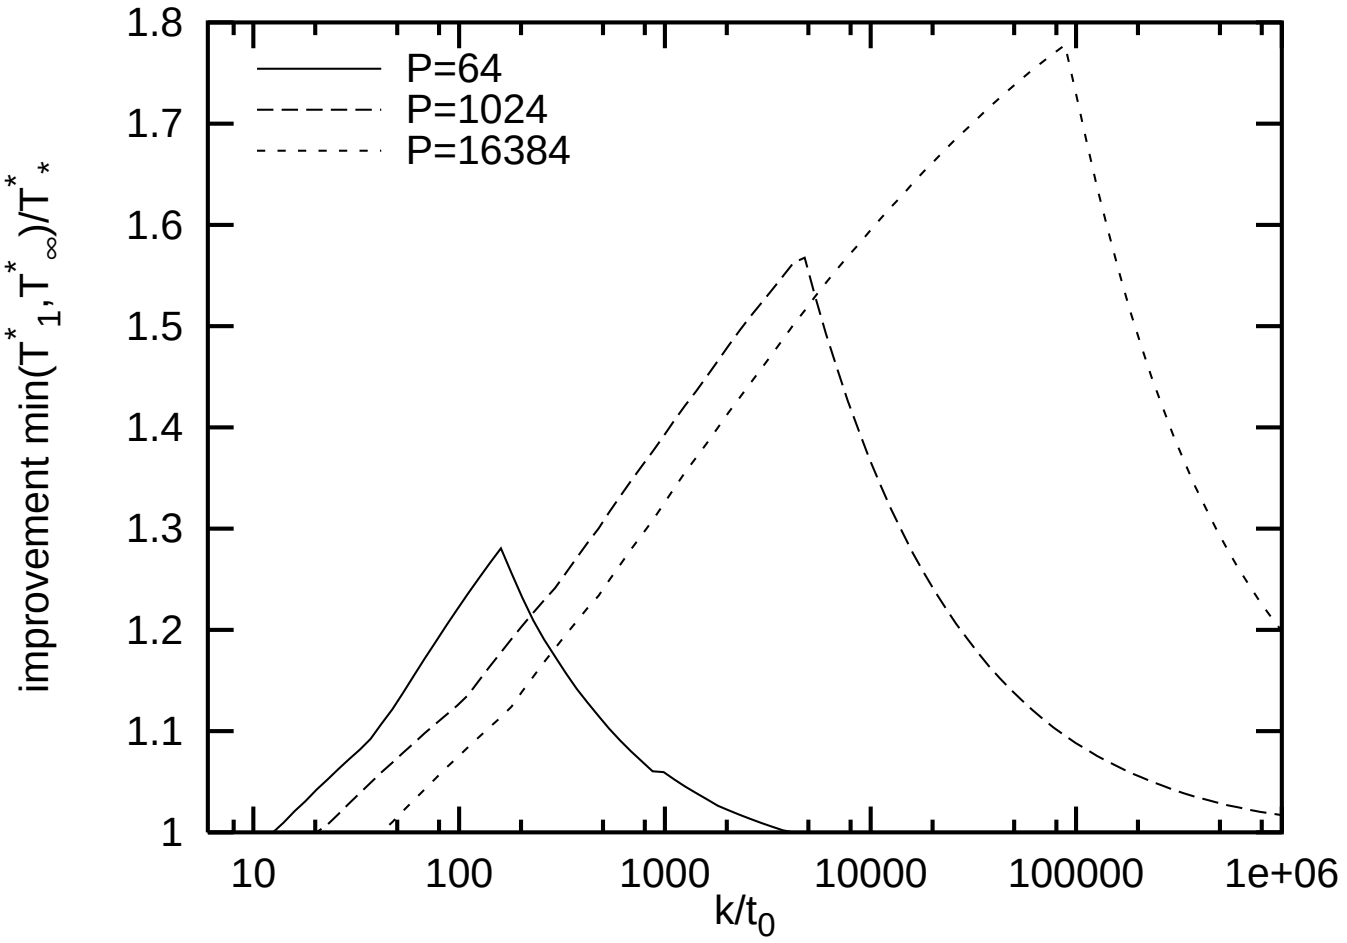
y Axis

vertical size: weighted average of the slants of the line segments in the figure should be about 45° [Cleveland 94]



y Axis

graph a bit wider than high, e.g., golden ratio [Tufte 83]



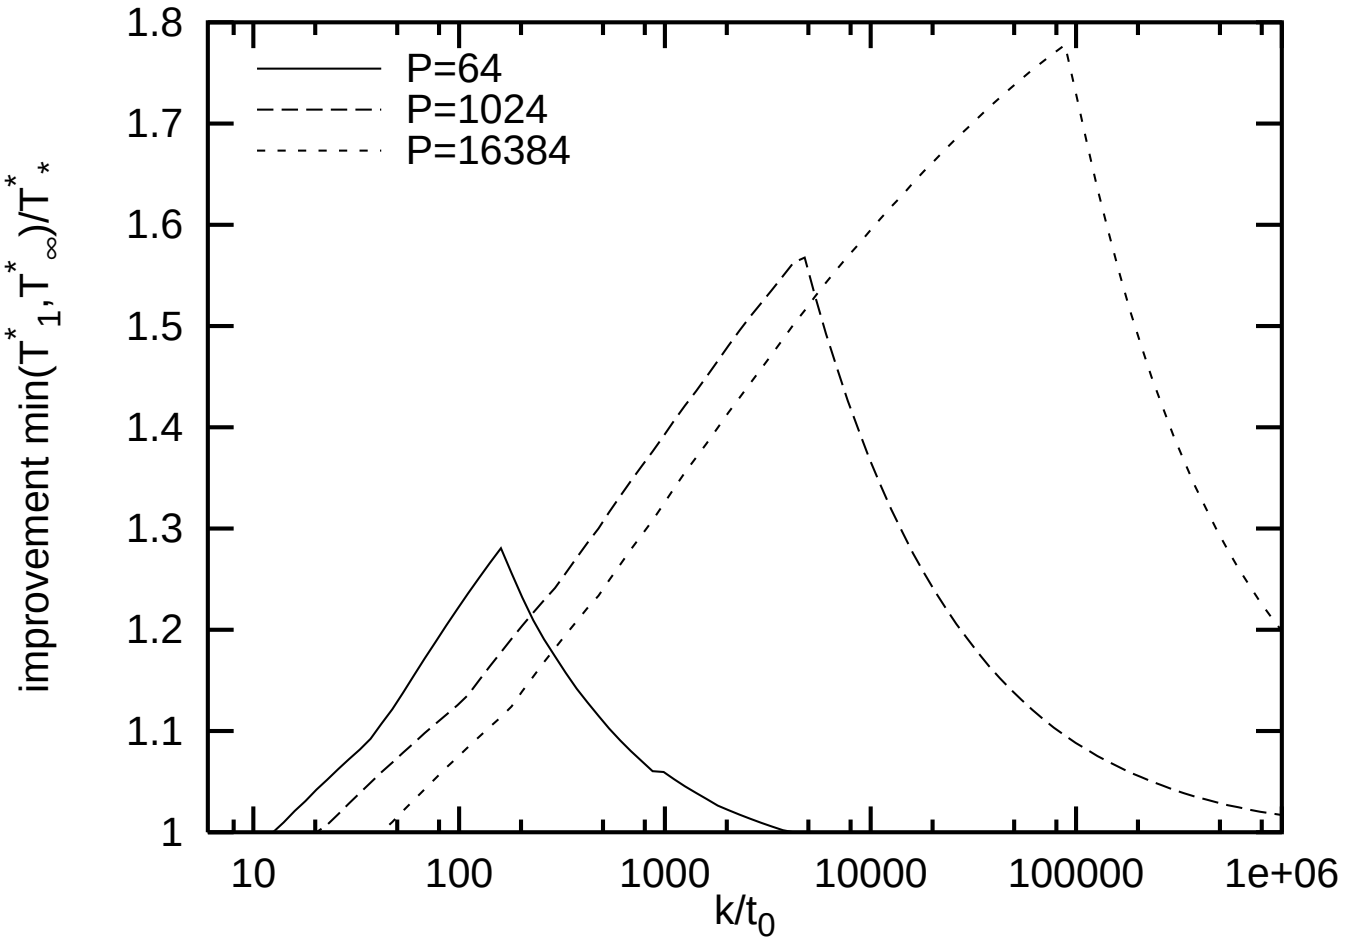
Multiple Curves

- $+$ high information density
- $+$ better than 3D (reading off values)
- $-$ Easily overdone

≤ 7 smooth curves

Reducing the Number of Curves

use ratios



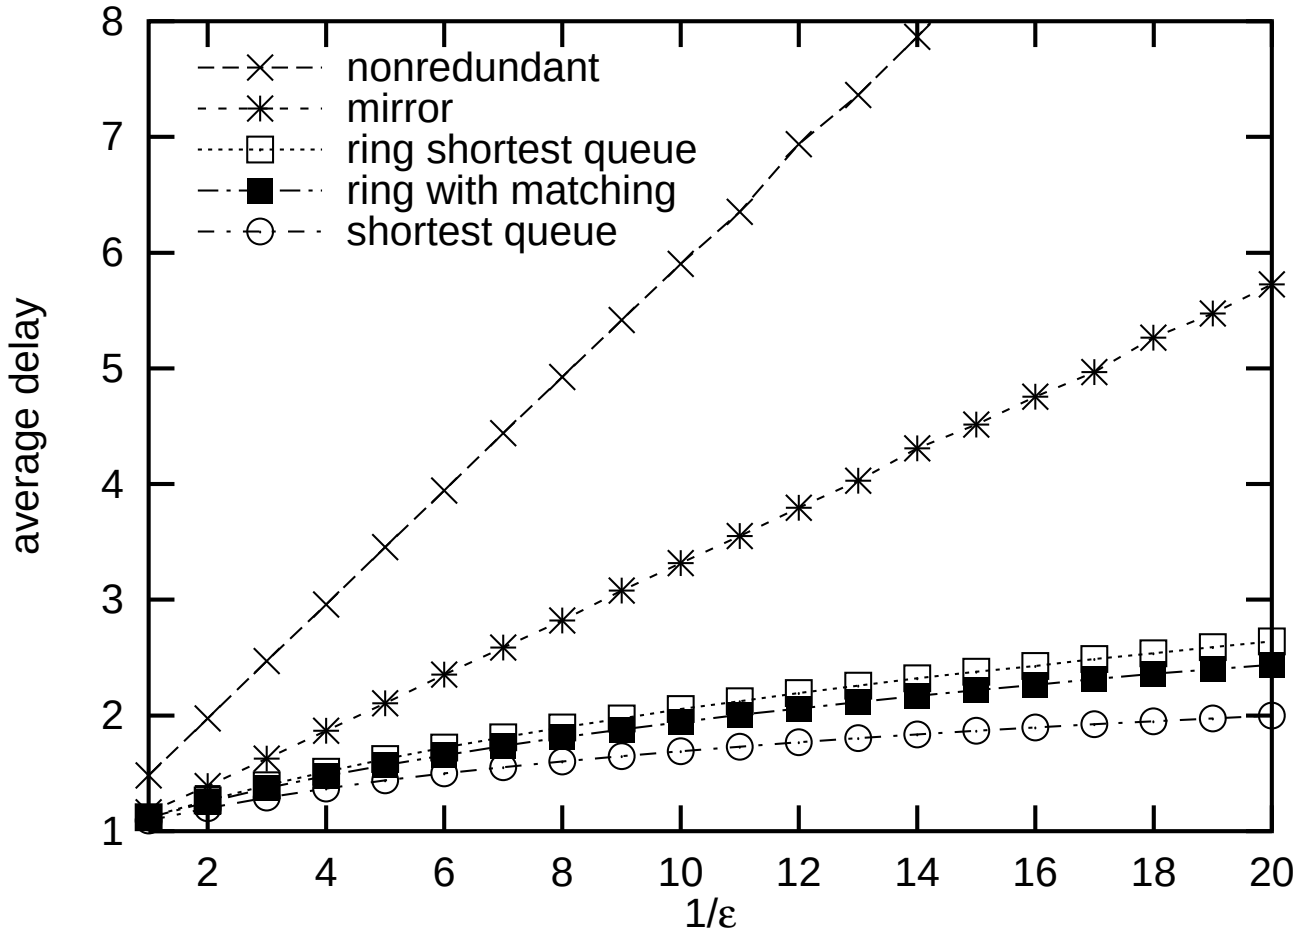
Reducing the Number of Curves

omit curves

- outclassed algorithms (for case shown)
- equivalent algorithms (for case shown)

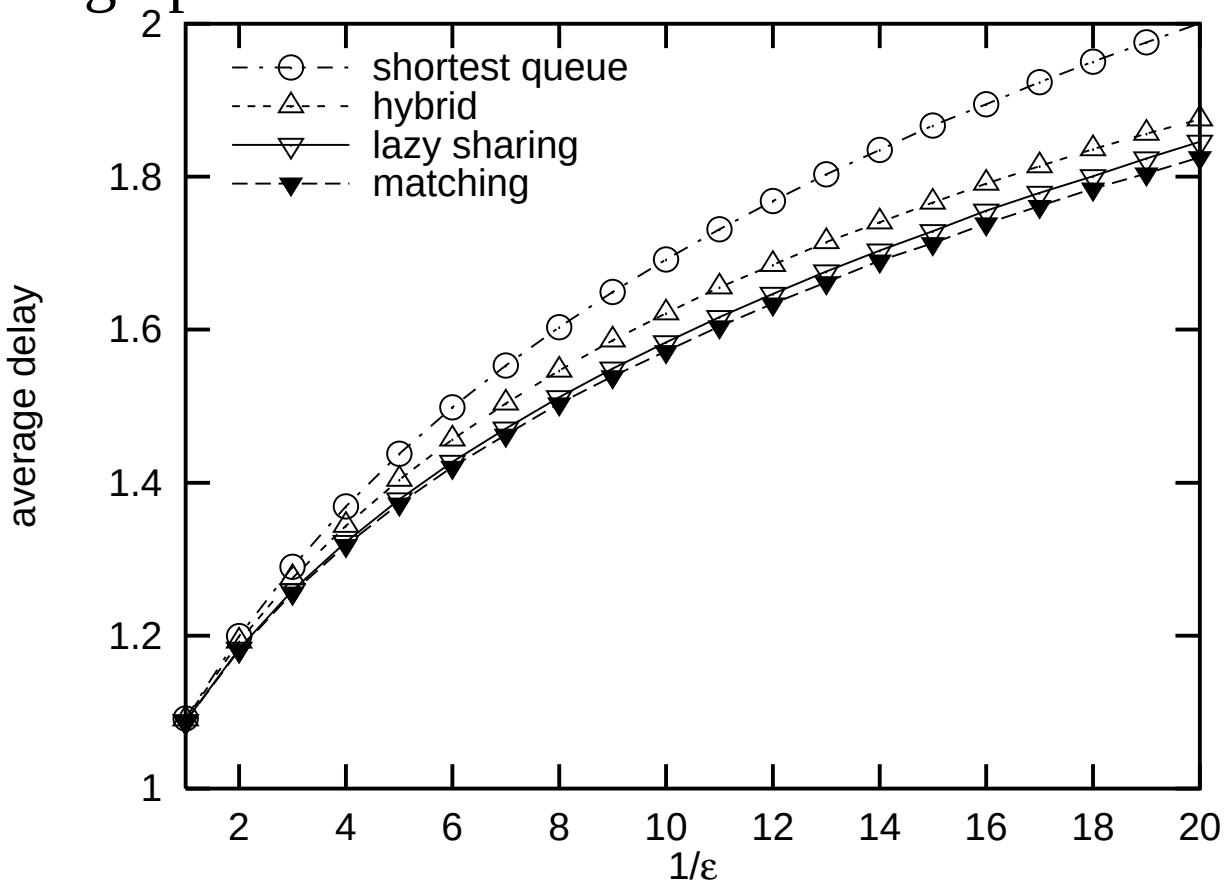
Reducing the Number of Curves

split into two graphs

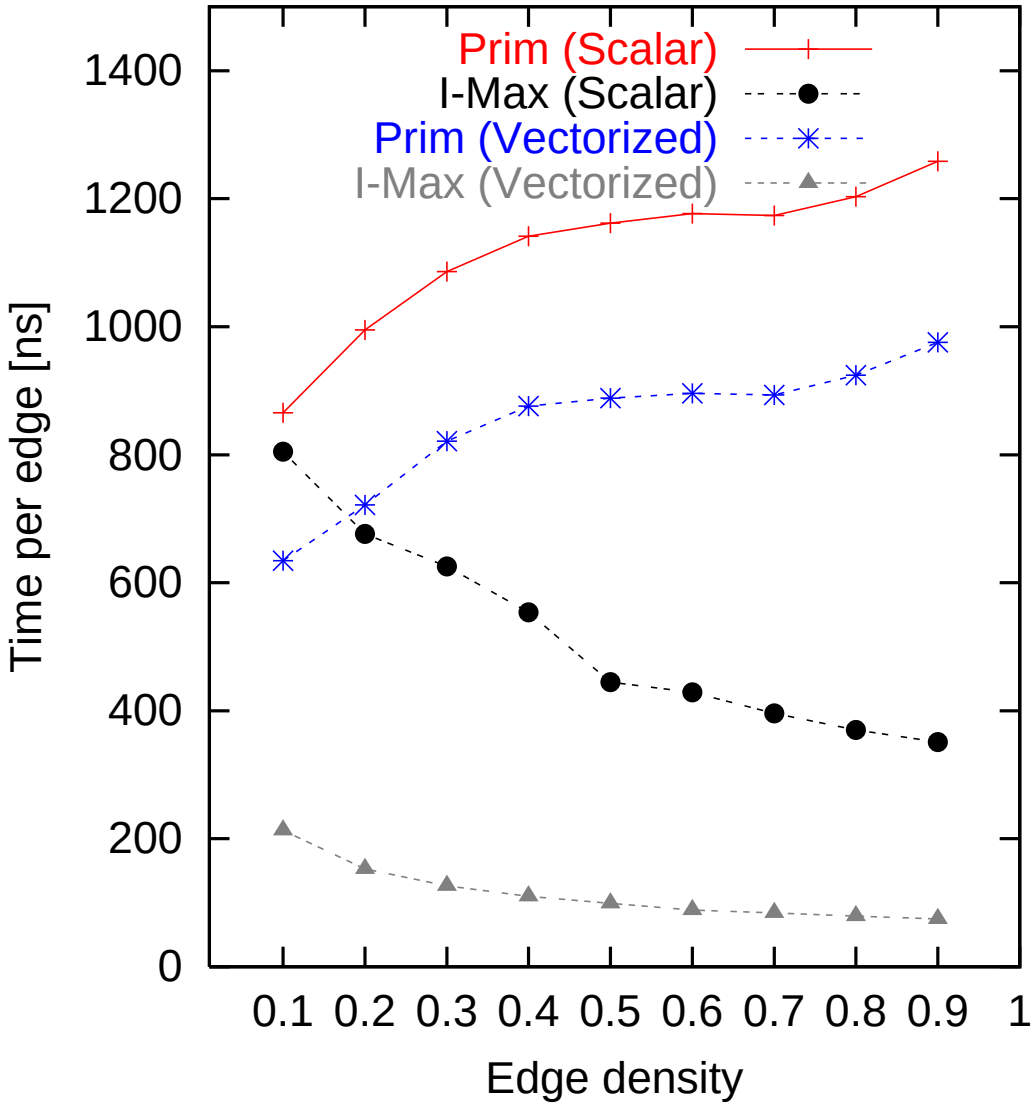


Reducing the Number of Curves

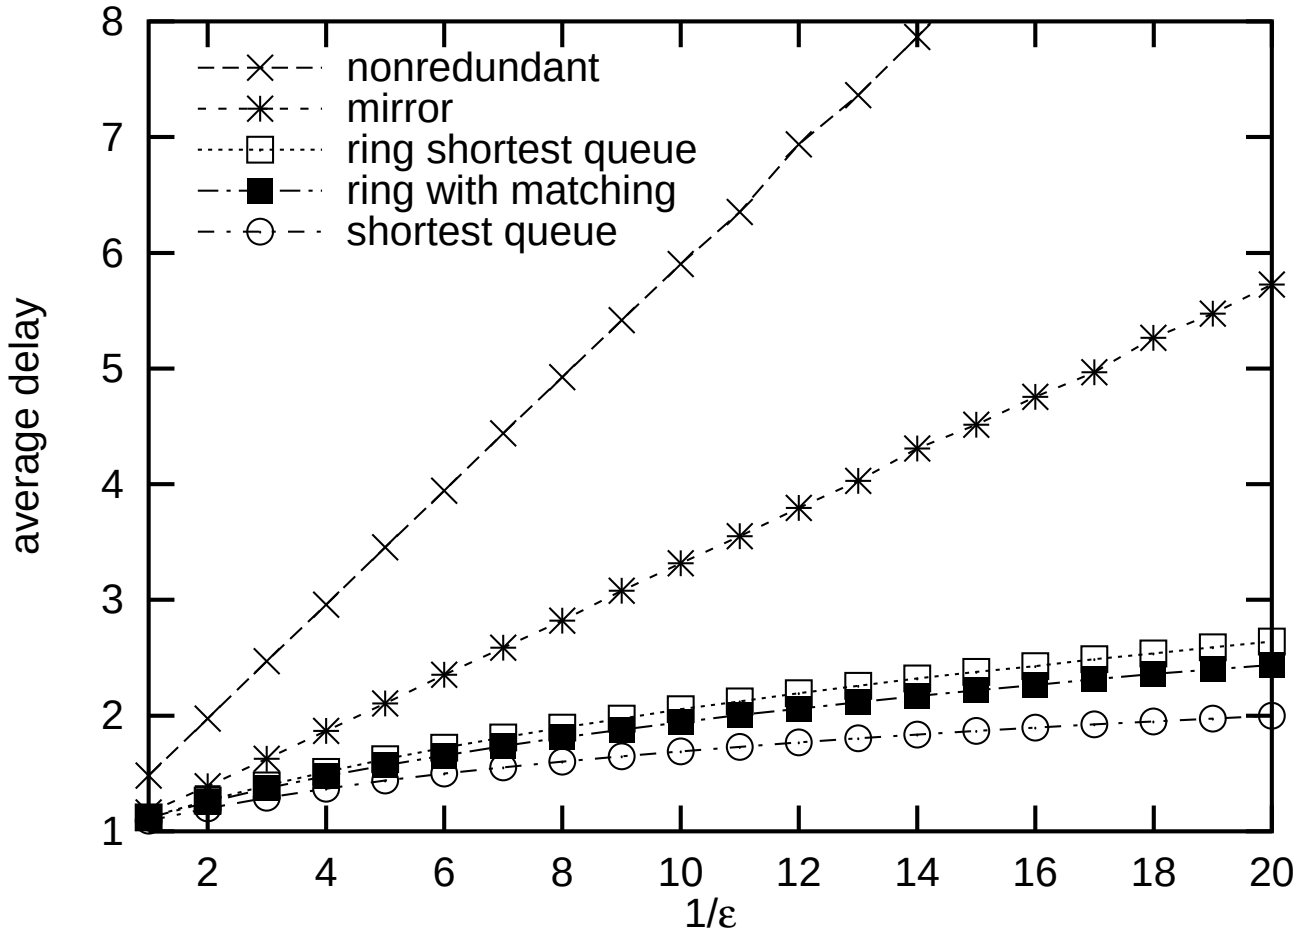
split into two graphs



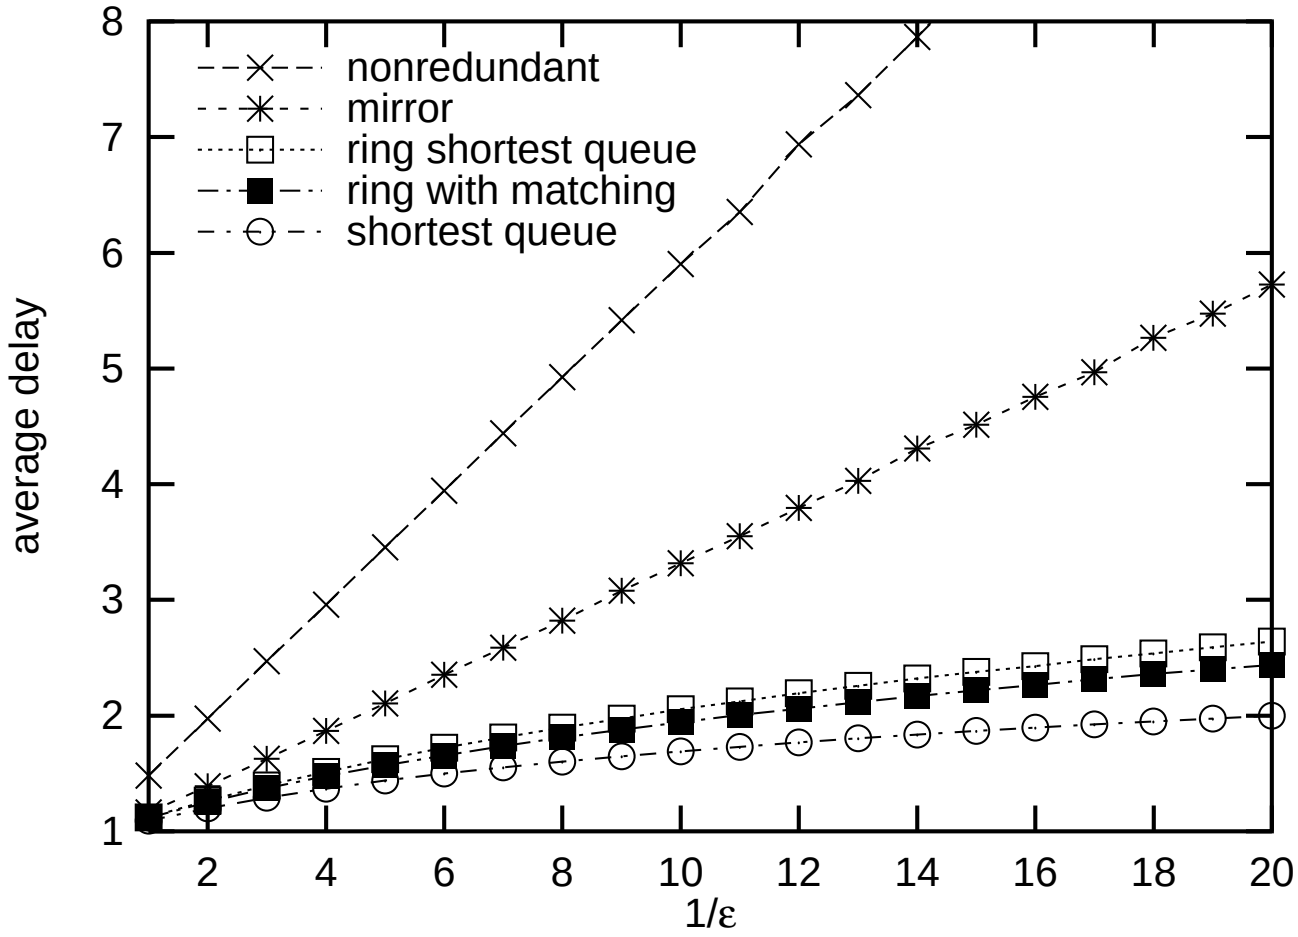
Keeping Curves apart: log y scale



Keeping Curves apart: smoothing



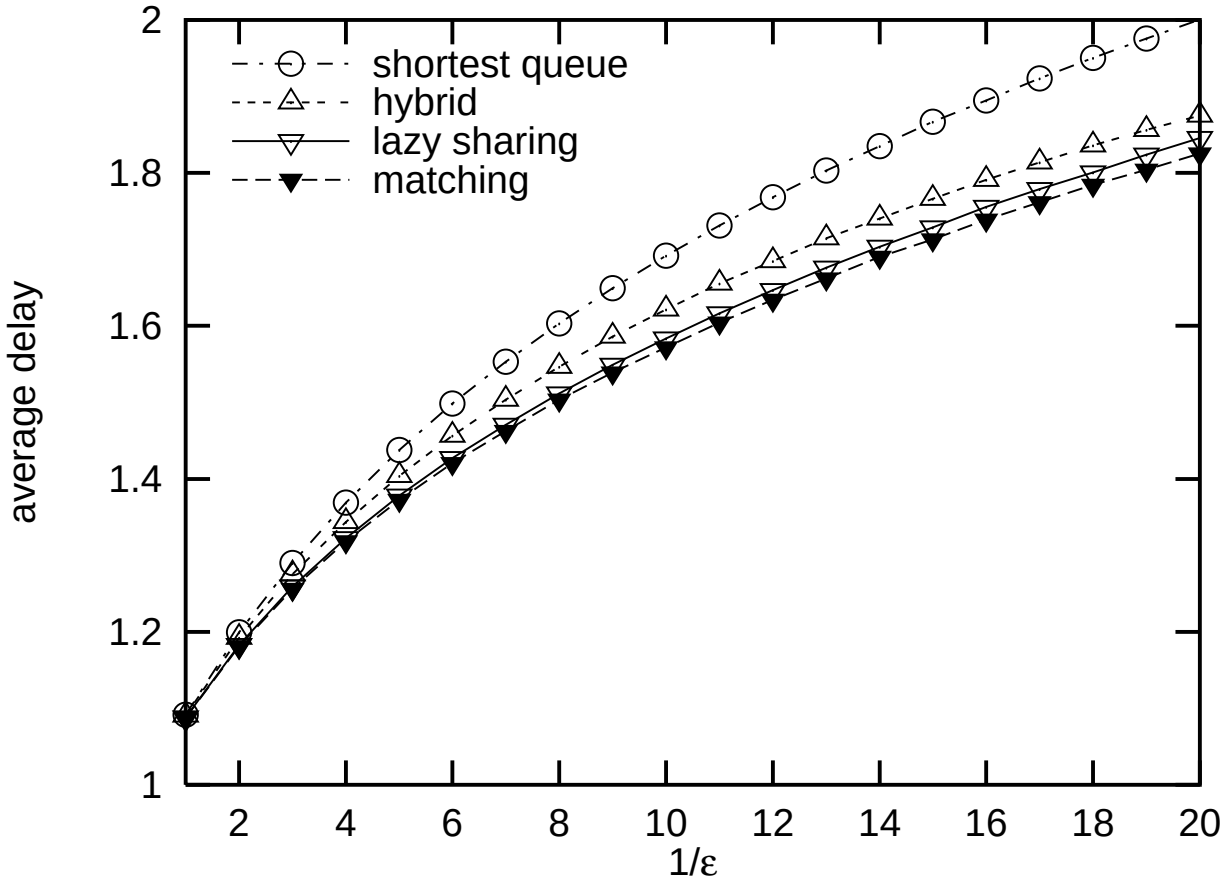
Keys



same order as curves

Keys

place in white space



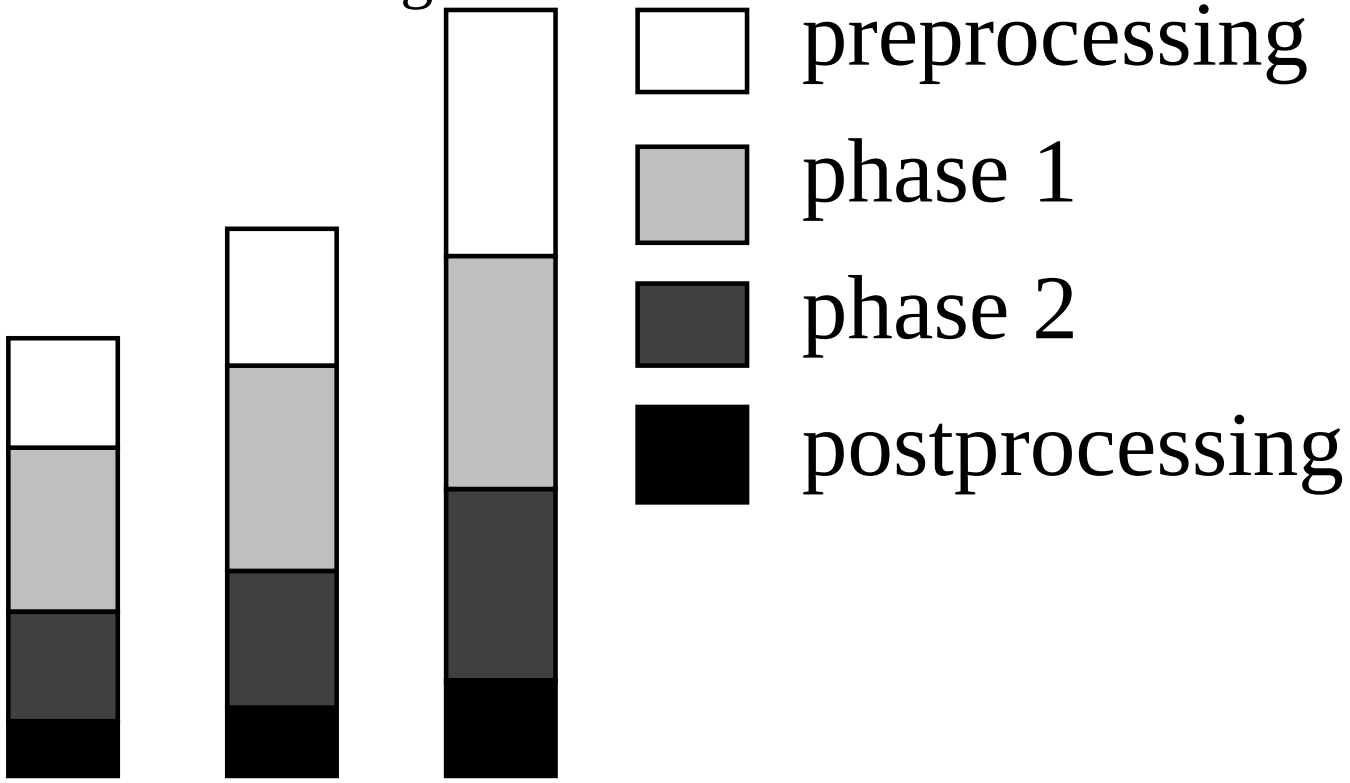
consistent in different figures

Todsünden

1. forget explaining the axes
2. connecting unrelated points by lines
3. mindless use/overinterpretation of double-log plot
4. cryptic abbreviations
5. microscopic lettering
6. excessive complexity
7. pie charts

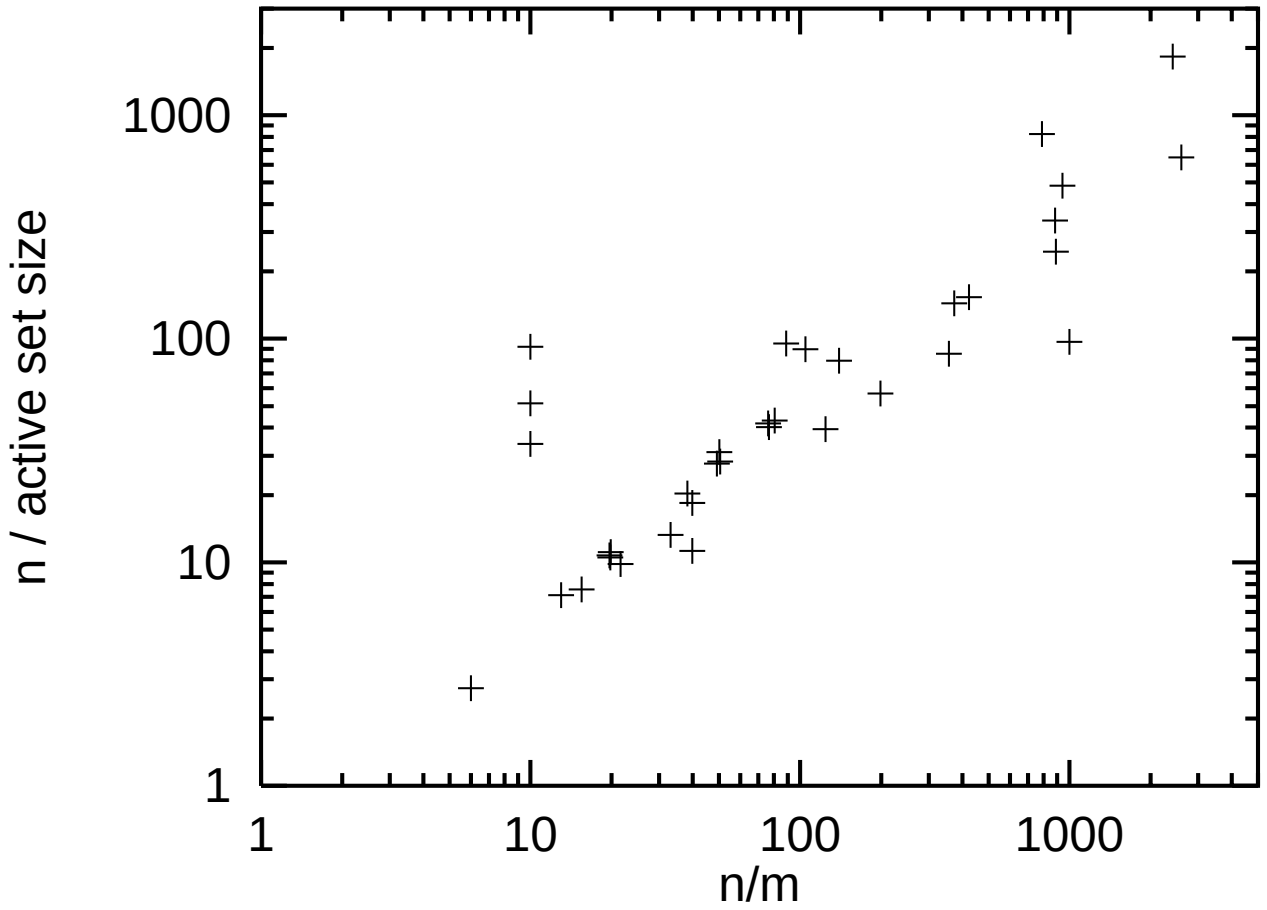
Arranging Instances

- bar charts
- stack components of execution time
- careful with shading



Arranging Instances

scatter plots

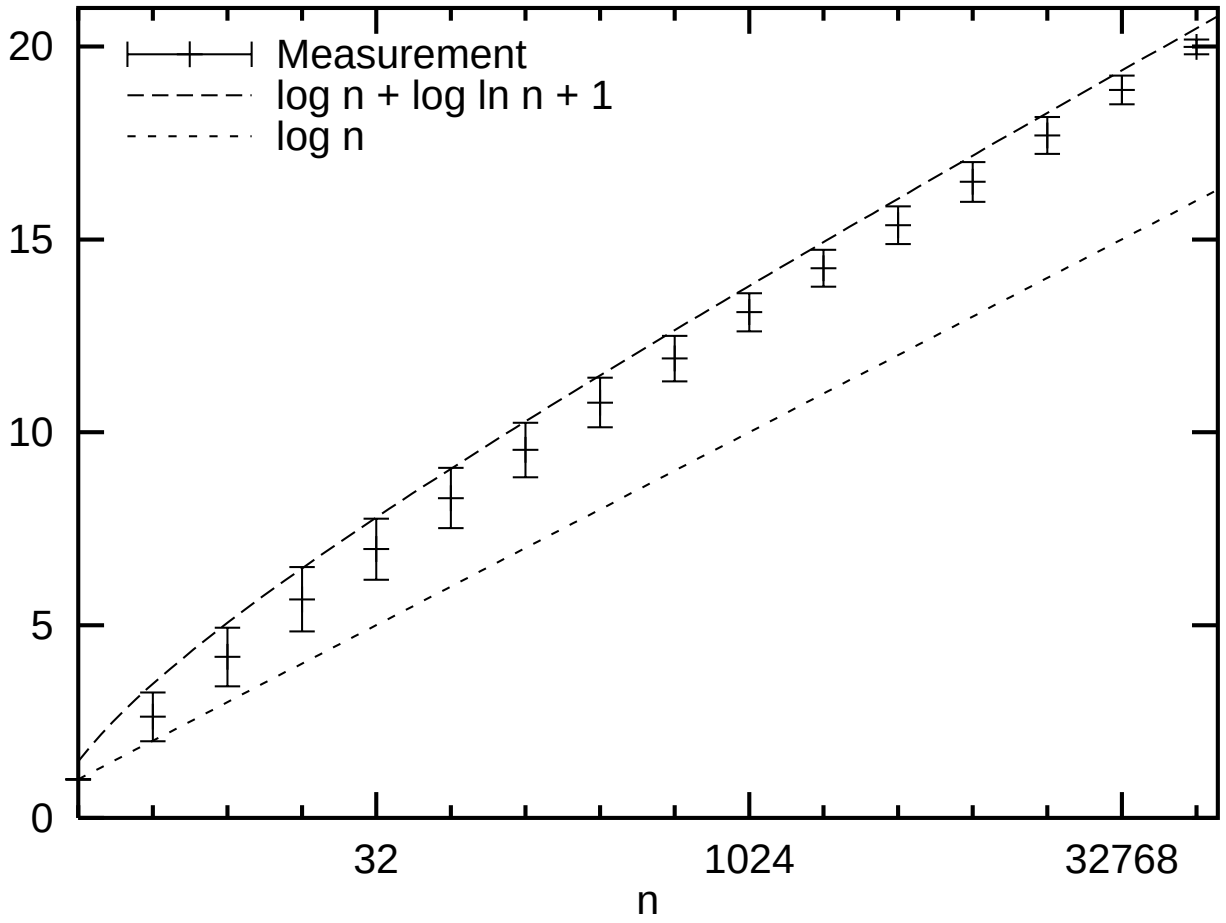


Measurements and Connections

- straight line between points do not imply claim of linear interpolation
- different with higher order curves
- no points imply an even stronger claim. Good for very dense smooth measurements.

Grids and Ticks

- Avoid grids or make it light gray
- usually round numbers for tic marks!
- sometimes plot important values on the axis



errors may not be of statistical nature!

3D

- you cannot read off absolute values
- interesting parts may be hidden
- only one surface
+ good impression of shape

surrounding text has more.

Check List

- ☐ Should the experimental setup from the exploratory phase be redesigned to increase conciseness or accuracy?
- ☐ What parameters should be varied? What variables should be measured? How are parameters chosen that cannot be varied?
- ☐ Can tables be converted into curves, bar charts, scatter plots or any other useful graphics?
- ☐ Should tables be added in an appendix or on a web page?
- ☐ Should a 3D-plot be replaced by collections of 2D-curves?
- ☐ Can we reduce the number of curves to be displayed?
- ☐ How many figures are needed?

- Scale the *x*-axis to make *y*-values independent of some parameters?
- Should the *x*-axis have a logarithmic scale? If so, do the *x*-values used for measuring have the same basis as the tick marks?
- Should the *x*-axis be transformed to magnify interesting subranges?
- Is the range of *x*-values adequate?
- Do we have measurements for the right *x*-values, i.e., nowhere too dense or too sparse?
- Should the *y*-axis be transformed to make the interesting part of the data more visible?
- Should the *y*-axis have a logarithmic scale?

- Is it be misleading to start the y-range at the smallest measured value?
- Clip the range of y-values to exclude useless parts of curves?
- Can we use banking to 45°?
- Are all curves sufficiently well separated?
- Can noise be reduced using more accurate measurements?
- Are error bars needed? If so, what should they indicate? Remember that measurement errors are usually not random variables.
- Use points to indicate for which x-values actual data is available.
- Connect points belonging to the same curve.

- Only use splines for connecting points if interpolation is sensible.
- Do not connect points belonging to unrelated problem instances.
- Use different point and line styles for different curves.
- Use the same styles for corresponding curves in different graphs.
- Place labels defining point and line styles in the right order and without concealing the curves.
- Captions should make figures self contained.
- Give enough information to make experiments reproducible.
