

# Lecture 10: Lowest Common Ancestors

Johannes Fischer

# Lowest Common Ancestors

# Some Initial Thoughts

- store only tree:  
⇒  $O(n)$  w.c. query time
- store all  $\Theta(n^2)$  answers:  
⇒  $O(1)$  query time
- **difficulty:**
  - ▶  $O(1)$  query time with  $O(n)$  space
  - ▶ lecture "Text Indexing" (SS'12 & SS'13)
  - ▶ here: **distributed** data structure

# Distributed Data Structures

- no access to **global** data structures
  - minimize **communication overhead**
- **labeling scheme:**
  - ▶ assign label  $l(v)$  to each node  $v$
  - ▶ compute  $l(\text{LCA}(x,y))$  from  $l(x)$  and  $l(y)$
- **goal:**
  - ▶ short labels
  - ▶ fast query time

# Simple Tree Labelings: parent(x,y)

parent(x,y) iff  
first lg n bits of I(x)  
= 2nd lg n bits of I(y)

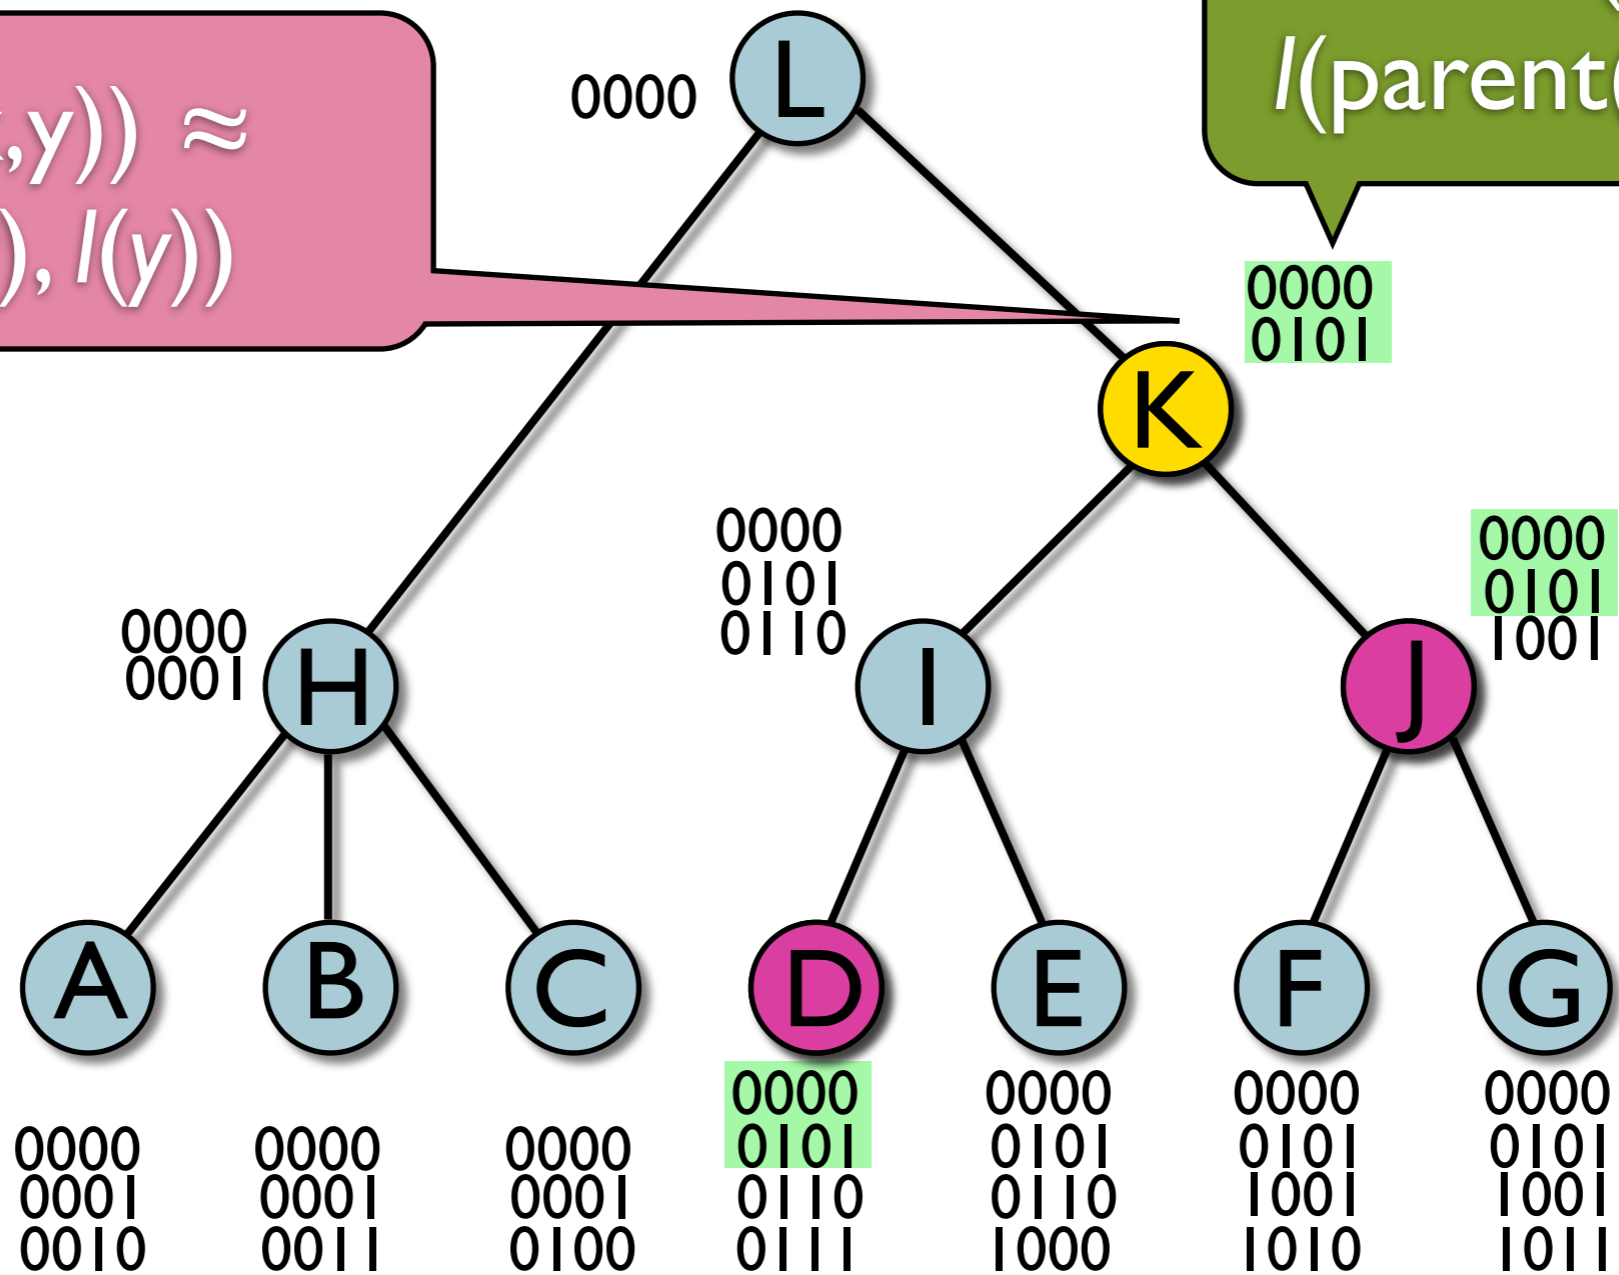

# Simple Tree Labelings:

## LCA(x,y)

$$I(\text{LCA}(x,y)) \approx \text{LCP}(I(x), I(y))$$

$$I(v) = I(\text{parent}(v)) \cdot \text{DFS}(v)$$

# Simple LCA-Labeling

- longest label length:
  - ▶ between  $O(\lg^2 n)$  and  $O(n \lg n)$  bits
  - ⇒ cannot even compute LCP in  $O(l)$  time
- in the following:
  - ▶ label length  $O(\lg n)$  bits
  - ▶  $O(l)$  query time

# Definitions

- node  $v$ :
  - ▶  $p(v)$  = parent of  $v$
  - ▶  $c(v)$  = set of  $v$ 's children
  - ▶  $size(v)$  = #nodes in  $v$ 's subtree  $T_v$
- **heavy** nodes:
  - ▶ having largest subtree among its siblings
  - ▶  $u$  heavy if  $size(u) = \max\{size(w) : w \in c(p(u))\}$
  - ▶ take arbitrary child if max not unique
- all other nodes: **light** (incl. root)

# Heavy Paths

- heavy nodes divide  $T$  into **heavy paths**:
  - ▶ from light node follow heavy nodes
  - ▶ continue recursively
  - ▶ **heavy path decomposition**
- $\langle v_1, v_2, \dots, v_k \rangle$  heavy path
  - ▶  $v_1 = a(v_i)$  is the **apex** of  $v_i$  for all  $i$
- **light size** of  $v$ :
  - $lsize(v) = size(v) - size(w)$  if  $w$  is  $v$ 's heavy child

# Labels

- **heavy label**  $hl(v)$ 
  - ▶ to any node  $v$
  - ▶ different for two nodes on one heavy path
  - ▶ can determine if  $i < j$  from  $v_i, v_j$  on  $\langle v_1, v_2, \dots, v_k \rangle$
- **light label**  $ll(v)$ :
  - ▶ only to light nodes  $v$
  - ▶ different for nodes with same parent
- **label**  $l(v) = l(p(a(v))) \cdot ll(a(v)) \cdot hl(v)$

# Answering $LCA(x,y)$

- compute LCP of  $l(x)$  and  $l(y)$
- 2 cases
  - ▶ depending on whether **mismatch** occurs in  $h_l$  or  $h_r$
  - ▶ need **helper label** ( $0 \triangleq h_l, 1 \triangleq h_r$ )
- see blackboard

# Analysis: Idea

- $hl(v)$  **repeated** in all nodes below  $v$  apart from those below heavy child

$\Rightarrow$   $hl(v)$  occurs  $lsize(v)$  times

$\rightsquigarrow$  use **shorter** heavy labels for **large lsizes**

- $ll(v)$  occurs in all nodes below  $v$

$\Rightarrow$   $ll(v)$  occurs  $size(v)$  times

$\rightsquigarrow$  use **shorter** light labels for **large subtrees**

# Precise Analysis

- see blackboard
